Amended Safety Assessment of Dialkyl Sulfosuccinate Salts as Used in Cosmetics

Status: Final Amended Report
Release Date: October 4, 2013
Panel Meeting Date: September 9-10, 2013

The 2013 Cosmetic Ingredient Review Expert Panel members are: Chairman, Wilma F. Bergfeld, M.D., F.A.C.P.; Donald V. Belsito, M.D.; Ronald A. Hill, Ph.D.; Curtis D. Klaassen, Ph.D.; Daniel C. Liebler, Ph.D.; James G. Marks, Jr., M.D., Ronald C. Shank, Ph.D.; Thomas J. Slaga, Ph.D.; and Paul W. Snyder, D.V.M., Ph.D. The CIR Director is Lillian J. Gill, D.P.A. This safety assessment was prepared by Monice M. Fiume, Senior Scientific Analyst/Writer, and Bart A. Heldreth, Ph.D., Chemist.

ABSTRACT

The CIR Expert Panel assessed the safety of eight dialkyl sulfosuccinate salts for use in cosmetics, finding that these ingredients are safe in cosmetics in the present practices of use and concentration when formulated to be non-irritating. The dialkyl sulfosuccinate salts primarily function as surfactants in cosmetics. The Panel reviewed the new and existing available animal and clinical data in making its determination of safety. The Panel found it appropriate to extrapolate the data on diethylhexyl sodium sulfosuccinate to assess the safety of the entire group because all of the diesters are of a similar alkyl chain length, all are symmetrically substituted, and all have similar functions in cosmetic formulations.

INTRODUCTION

Diethylhexyl sodium sulfosuccinate (previously named dioctyl sodium sulfosuccinate) was reviewed by the Cosmetic Ingredient Review (CIR) Expert Panel (Panel) in 1994, and a safe concentration limit of 0.42% was established. A petition to open the report to review new clinical data was received, and in 1998, the Panel amended the report to conclude that this ingredient is safe as used in cosmetic formulations. In the discussion, the Panel stressed that care should be taken to avoid irritancy, especially in those products intended for prolonged contact with the skin.

The International Cosmetic Ingredient Dictionary and Handbook lists seven additional dialkyl sulfosuccinate salts. All the dialkyl sulfosuccinate salts are anionic surfactants, and the Panel determined that the data on diethylhexyl sodium sulfosuccinate can be extrapolated to support the safety of these seven salts:

- Ammonium Dinonyl Sulfosuccinate
- Diamyl Sodium Sulfosuccinate
- Dicapryl Sodium Sulfosuccinate
- Diheptyl Sodium Sulfosuccinate
- Dihexyl Sodium Sulfosuccinate
- Diisobutyl Sodium Sulfosuccinate
- Ditridecyl Sodium Sulfosuccinate

Published literature that have become available since the CIR safety assessment was issued in 1998 are presented in this review. Data from 1998 report on diethylhexyl sodium sulfosuccinate are summarized in Table 1; because data from the existing safety assessment are available in Table 1, only new data are included in the body of this safety assessment.

CIR has not reviewed and concluded on the safety of all of the individual alcohol constituents that make up the sulfosuccinate salts. However, data on caprylic, isobutyl, and ethylhexyl alcohols, which are constituents of a few of the dialkyl sulfosuccinate salts, have been summarized in previous CIR reviews. Accordingly, these data are provided in Table 2.

CHEMISTRY

Definition and Structure

The ingredients included in this review are the salts of diesters of 2-sulfosuccinic acid. The ingredients all share a sulfosubstituted, succinic acid core; accordingly, these salts are sulfosuccinates. For example, diheptyl sodium sulfosuccinate consists of a seven-carbon alkyl chain (heptyl), bonded to the sulfosuccinate core via an ester linkage, and followed by an ester linkage to an additional seven-carbon alkyl chain.

![Figure 1. Dihexyl Sodium Sulfosuccinate](image_url)

Due to the ester linkage, these sulfosuccinate ingredients are theoretically sensitive to hydrolysis, especially under acidic conditions.

The dialkyl sulfosuccinate salts included in this assessment are defined in Table 3, and the structures are depicted following the text of this document.

Physical and Chemical Properties

Little published physical and chemical properties data were found. The data that were available are provided in Table 4.
Method of Manufacture

Diethylhexyl Sodium Sulfonate

Refer to Table 1 for summary information from the original safety assessment on the method and manufacture of diethylhexyl sodium sulfosuccinate.

In the production of diethylhexyl sodium sulfosuccinate, malic acid and 2-ethylhexanol are reacted to form the diester, which is sulfonated using sodium metabisulfite. The reaction takes place in a closed system that is opened only for the addition of the reactants.

Dialkyl Sodium Sulfosuccinate

The dialkyl sodium sulfosuccinates are prepared by the action of the appropriate alcohols on maleic anhydride followed by the addition of sodium bisulfite.

Impurities

Diethylhexyl Sodium Sulfosuccinate

The Food Chemicals Codex has the following acceptance criteria for diethylhexyl sodium sulfosuccinate: not less than (NLT) 98.5% C_{20}H_{37}NaO_7S; not more than (NMT) 2 mg/kg lead; NMT 0.2% bis(2-ethylhexyl)maleate; NMT 2.0% loss on drying; 15.5-16.2% residue on ignition. The United States Pharmacopeia acceptance criteria are: NLT 99.0% and NMT 100.5% C_{20}H_{37}NaO_7S calculated on the anhydrous basis; NMT 2.0% water; NMT 0.001% heavy metals; NMT 0.4% bis(2-ethylhexyl)maleate; and 15.5-16.5% residue on ignition, calculated on the anhydrous basis.

USE

Cosmetic

The dialkyl sulfosuccinate salts are reported to function in cosmetics as surfactants (Table 3). The Food and Drug Administration (FDA) collects information from manufacturers on the use of individual ingredients in cosmetics as a function of cosmetic product category in its Voluntary Cosmetic Registration Program (VCRP). VCRP data obtained from the FDA in 2013, and data received in response to a survey of the maximum reported use concentration by category conducted by the Personal Care Products Council (Council), indicate that diethylhexyl sodium sulfosuccinate is the only dialkyl sulfosuccinate salt in use.

Diethylhexyl sodium sulfosuccinate is used in hair spray formulations at a concentration of 0.15% in an aerosol and at 0.25% in pump spray formulations. In practice, 95% to 99% of the droplets/particles released from cosmetic sprays have aerodynamic equivalent diameters >10 µm, with propellant sprays yielding a greater fraction of droplets/particles <10 µm compared with pump sprays. Therefore, most droplets/particles incidentally inhaled from cosmetic sprays would be deposited in the nasopharyngeal and thoracic regions of the respiratory tract and would not be respirable (i.e., they would not enter the lungs) to any appreciable amount.

All of the dialkyl sulfosuccinate salts named in this report appear in the European Commission database with information on cosmetic ingredients and substances (CosIng) inventory. Listing in the inventory does not indicate the ingredients are actually used in cosmetic products or approved for such use.

Non-Cosmetic

Sodium 1,4-dialkyl sulfosuccinates are exempt from the requirement of a tolerance for residues when used as an inert ingredient in pesticide formulations for pre-harvest and post-harvest uses, as well as for application to animals under 40 CFR 180.910 and 40 CFR 180.930, respectively. This regulation eliminates the need to establish a maximum permissible level for residues of the sodium 1,4-dialkyl sulfosuccinates.

Diethylhexyl Sodium Sulfosuccinate

Diethylhexyl sodium sulfosuccinate is generally recognized as safe and effective as a laxative drug product for over-the-counter use. (58 FR 46589, Sept 2, 1993).

Diethylhexyl sodium sulfosuccinate is included in the Listing Of Color Additives Exempt From Certification; it is used as a diluent in color additive mixtures for food use exempt from certification, and has a limitation of <9 ppm. (21CFR 73.1) It is approved as the direct food additive “cocoa with dioctyl sodium sulfosuccinate for manufacturing,” whereby the amount of diethylhexyl sodium sulfosuccinate does not exceed 75 parts per million of the finished beverage (21CFR 172.520). Diethylhexyl sodium sulfosuccinate is also allowed as a multi-purpose food additive when it meets the specifications of the Food
Absorption, Distribution, Metabolism, and Excretion

The metabolism and excretion of diethylhexyl sodium sulfosuccinate was determined in rats in several studies; limited details were available. Albino rats were given a single oral dose of 50 mg/kg bw of [35S]diethylhexyl sodium sulfosuccinate in an alcohol and water (1:1) solution. More than 85% of the diethylhexyl sodium sulfosuccinate was excreted within 24-48 h after dosing, and all was excreted within 96-120 h. The majority of the radioactivity, 66%, was excreted in the feces. Only 25-35% of the dose was excreted in the urine, and that was within 24-48 h after dosing. At 96-168 h after dosing, only trace amounts of radioactivity were found in the tissues.

However, in other studies, the feces were not the primary route of excretion. In a study in which two rats were given a single oral dose of 5 mg per kg bw of [14C]diethylhexyl sodium sulfosuccinate, 64.1% of the radioactivity was excreted in the urine and 37.4% in the feces in the first 24 h, and then only approximately 1% in the urine and 0.9% in the feces in the next 24 h. The researchers stated that diethylhexyl sodium sulfosuccinate must undergo extensive metabolism in the rat because no unchanged diethylhexyl sodium sulfosuccinate was found in the urine, and only a small amount was present in the feces.

Metabolism and excretion was also determined in rabbits and dogs; as with the rat studies, limited details were available. One female rabbit and one male Beagle dog were each given a single oral dose, and one of each species was given a single i.v. dose of 4 mg [14C]diethylhexyl sodium sulfosuccinate. In the rabbits, within 24 h, 87% and 69.7% of the radioactivity was excreted in the urine following oral and i.v. dosing, respectively, and similar patterns of metabolites were found with both routes of administration.

In the dogs, similar excretion patterns and metabolic profiles were observed for both routes of dosing. Approximately 21% of the radioactivity was excreted in the urine in the first 24 h. The majority of the radioactivity, approximately 70%, was excreted in the feces at 24-48 h post-dosing. Blood samples were analyzed for 2-ethylhexanol compounds; with i.v. administration, the blood levels fell rapidly during the first hour, and none was found after 8 h. Similarly, following oral administration, small amounts of 2-ethylhexanol was found in the blood after 1 h, and none was found after 8 h.

Penetration Enhancement
Surfactants can enhance the permeation rate of various compounds, inducing a concentration-dependent biphasic action with respect to altering skin permeability. Surfactant molecules must diffuse through the lipid region of the stratum corneum in order to interact with the deeper protein-rich areas. Anionic surfactants can solubilize the less-soluble protein, or they can remain on the skin due to formation of chemical compounds with skin keratin, and they can interact strongly with both keratin and lipids. If exposure time is short, permeation through the stratum corneum by anionic materials is generally poor; however, permeation increases with a longer exposure time.

The effect of a diethylhexyl sodium sulfosuccinate microemulsion on the distribution of the polyphenols curcumin and resveratrol between the epidermis and dermis was examined in excised guinea pig and Yucatan micropig (YMP) skin. The microemulsion consisted of 150 mM saline solution, isopropyl palmitate, diethylhexyl sodium sulfosuccinate, and ethanol, with a weight ratio of 20.2:31.3:33.3:15.2, and the mean particle size was 16.6 ± 1.8 nm. Franz-type diffusion cells were used, and 0.5 ml (guinea pig skin) or 1 ml (YMP skin) of the vehicle containing each polyphenol was added to the donor compartment as saturated concentration; the available diffusion area was approximately 0.62 cm². Vehicles consisting of a...
Tween 80 microemulsion or isopropyl myristate were also evaluated. Treatment time was 20 h for guinea pig skin and 40 h for YMP skin. The accumulation of the polyphenols in guinea pig and YMP skin was statistically significantly increased using diethylhexyl sodium sulfosuccinate microemulsion as the vehicle, as compared to that found with the Tween 80 microemulsion or isopropyl myristate. Approximately 1.7% curcumin and 2.2% resveratrol added to donor compartments were incorporated into the skin by the diethylhexyl sodium sulfosuccinate microemulsion. Skin accumulation of curcumin in the diethylhexyl sodium sulfosuccinate microemulsion was approximately 1.9 µmol/g skin in guinea pig skin and approximately 0.24 µmol/g skin in YMP skin; in the isopropyl myristate vehicle, almost no curcumin accumulated in either skin-type. Skin accumulation of resveratrol in the microemulsion was approximately 12 µmol/g skin in guinea pig skin and approximately 3 µmol/g skin in YMP skin; in the isopropyl myristate vehicle, approximately 1 µmol/g skin accumulated in guinea pig skin and 0.1 µmol/g accumulated in YMP skin. In determining the distribution in guinea pig and YMP skin, it was found that diethylhexyl sodium sulfosuccinate, curcumin, and resveratrol penetrated deep in the skin. In YMP skin, the distribution ratio of the polyphenols between the dermis and epidermis decreased with increased molecular weight.

**TOXICOLOGICAL STUDIES**

**Single Dose (Acute) Toxicity**

**Dermal**

The dermal LD$_{50}$ of undiluted diethylhexyl sodium sulfosuccinate in rabbits was >10 g/kg.\(^4\) Occlusive patches of 10 g/kg of the test material were applied to the clipped, unabraded, skin of five male New Zealand white rabbits. Skin fissuring, desquamation, and coriaceousness were observed.

**Oral**

Refer to Table 1 for a summary of single-dose oral toxicity data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

The oral LD$_{50}$ of diethylhexyl sodium sulfosuccinate in 4% acacia was 2.64 g/kg bw in male albino ARS/ICR mice.\(^{21}\) In guinea pigs, the oral LD$_{50}$ was approximately 0.65 g/kg bw aq. diethylhexyl sodium sulfosuccinate.\(^{22}\)

**Repeated Dose Toxicity**

**Dermal**

Refer to Table 1 for a summary of repeated-dose dermal toxicity data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

**Oral**

Refer to Table 1 for a summary of repeated-dose oral toxicity data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

A group of 20 male and 20 female albino rats were fed a diet containing 1% diethylhexyl sodium sulfosuccinate (100% pure) for 90 days, and controls were given untreated feed.\(^4\) All animals survived until study termination. There were no clinical signs of toxicity, and no dosing-related macroscopic or microscopic findings. Differences in body weights or organ weights compared to controls were not statistically significant.

Twelve rats/group were fed a diet containing 0, 0.5, 1.04, or 1.5% diethylhexyl sodium sulfosuccinate for 26 wks.\(^{23}\) Body weight gains of females of the 1.04 and 1.5% dose groups were decreased during wk 3. Two control animals and 4 animals of the 1.5% group died during the study; two of the four animals of the 1.5% group had hemorrhagic gastroenteritis. No other effects were noted. The no-observable adverse effect level (NOAEL) was 0.5%, and the lowest-observable adverse effect level was 1.04%.

Groups of four male and four female Beagle dogs were dosed orally with tablets containing 30 mg/kg bw diethylhexyl sodium sulfosuccinate, 10 mg/kg bw diethylhexyl sodium sulfosuccinate + 5 mg/kg bw 1,8-dihydroxyanthraquinone, or 30 mg/kg bw diethylhexyl sodium sulfosuccinate and 15 mg/kg bw 1,8-dihydroxyanthraquinone, daily, for 1 yr.\(^{21}\) A control group was given a placebo tablet. Urinalysis was performed, and hematological and clinical chemistry parameters were measured at various intervals. No signs of toxicity were observed in any of the groups. Diethylhexyl sodium sulfosuccinate, alone and in combination with 1,8-dihydroxyanthraquinone, did not have any adverse effects on urinalysis, hematological or clinical parameters, or body weights, and it did not induce any gross or microscopic lesions. The NOAEL was >30 mg/kg bw.

**Inhalation**

Refer to Table 1 for a summary of repeated-dose inhalation toxicity data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

Fluorescent latex particles, 0.63 µm diameter, were administered in aerosol form to 30 rabbits.\(^{24}\) Six rabbits were killed immediately after administration of the fluorescent particles (baseline group); 12 rabbits were given a diethylhexyl sodium sulfosuccinate aerosol prepared as a 2% solution in equal volumes of ethanol and physiological saline (detergent group) and 12 were given vehicle aerosol (control group). The detergent and control aerosols were administered as 200 pressure-con-
trolled breaths at a frequency of 40/min, resulting in deposition of approximately 10 µl of fluid in the lungs; aerosol administration was repeated after 90 min. Groups of six animals from the detergent and control groups were then exposed to large tidal volume ventilation (LTVV) or conventional ventilation for 3 h. The total number of particles in the alveoli and ducts were similar for all groups, except for a statistically significant decrease in the control LTVV group. All test groups had reduced number of single particles in the alveoli as compared to the baseline group. The number of clustered particles was statistically significantly increased in the alveoli + ducts in the detergent-LTVV group, as compared to the baseline group.

Rabbits were administered [99mTc]diethylene triamine pentaacetate (99mTc-DTPA) using a nebulizer, and the effect of diethylhexyl sodium sulfosuccinate on the absorption of this compound from the lungs was examined. The alveolo-capillary transfer of 99mTc-DTPA was measured for 30 min, and the rabbits were then nebulized with 0.2% solution of diethylhexyl sodium sulfosuccinate for 5 min. Thirty min later, the rabbits were nebulized with a 2% diethylhexyl sodium sulfosuccinate solution for 5 min. Diethylhexyl sodium sulfosuccinate greatly enhanced the alveolar absorption of 99mTc-DTPA.

**Ocular Irritation**

Refer to Table 1 for a summary of ocular irritation data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

Diethylhexyl sodium sulfosuccinate, 0.1 g, was instilled into the conjunctival sac of the eyes of six rabbits. The eyes were scored for irritation after 24, 48, and 72 h, and the following scores were reported: 11.66, 12.50, and 4.16, respectively, (cornea); 1.66 at all three times (iris); and 5.33, 4.33, and 1.66, respectively (conjunctivae). No destruction or irreversible changes of the tissue in 24 h were reported.

Diethylhexyl sodium sulfosuccinate, 10% (vehicle not specified), was used as a positive control in a Draize eye irritancy test. One-tenth ml of the test substance was instilled into the conjunctival sac of one eye of each of three rabbits for 2 sec; the eyes were rinsed. Diethylhexyl sodium sulfosuccinate, 10%, was severely irritating to rabbit eyes, inducing perforated damages.

Diisobutyl sodium sulfosuccinate is irritating to eyes and mucous membranes. (Details were not provided.)

**REPRODUCTIVE AND DEVELOPMENTAL TOXICITY**

Refer to Table 1 for a summary of reproductive developmental toxicity data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

In developmental toxicity studies, groups of 20 gravid female mice and 20 gravid female rats were dosed by gavage with 0, 16, 80, or 400 mg/kg bw of a test substance containing 0.4% (w/v) diethylhexyl sodium sulfosuccinate. The mice were dosed on days 6-15 and killed on day 17 of gestation and the rats were dosed on days 5-19 of gestation and killed on day 20 of gestation. The NOAEL for maternal toxicity and teratogenic effects for both mice and rats was 400 mg/kg bw of the test substance containing 0.4% (w/v) diethylhexyl sodium sulfosuccinate.

Groups of 20-39 gravid female Sprague-Dawley rats were fed a diet containing 0, 1, or 2% diethylhexyl sodium sulfosuccinate (equivalent to 0, 1074, and 1983 mg/kg bw, respectively) on days 6-15 of gestation, and the dams were killed on day 21 of gestation. No adverse effects on maternal or fetal parameters were observed in the 1% test group. In the 2% test group, significant incidences of resorptions and gross abnormalities, primarily exencephaly and, at times, spina bifida, anophthalmia, and associated skeletal defects, were reported. The NOAEL for maternal toxicity and teratogenic effects was 1%.

Groups of 30 female rats were dosed by gavage with 0, 16, 80, or 400 mg/kg bw of a test substance containing 0.4% (w/v) diethylhexyl sodium sulfosuccinate once daily for 14 days prior to mating with untreated males; one-half of the animals in each group were dosed until day 13 of gestation, at which time the animals were killed, and the remaining animals were dosed until parturition and were not killed. No effects on reproductive parameters, fertility, or pup weight and condition were observed. The parental NOAEL was 400 mg/kg bw of the test substance containing 0.4% (w/v) diethylhexyl sodium sulfosuccinate.

A three-generation study was performed in which male and female CFE rats were continuously fed a diet containing 0.5 and 1% of a test substance containing 50% diethylhexyl sodium sulfosuccinate in aq. beverage-grade ethanol; the control group was untreated. The number of animals per group was not stated. Dosing was initiated at weaning of rats of the F0 generation; these rats were mated twice to produce the F1a and F1b generation. Rats of the F1b generation were mated to produce the F2 generation, and the F2 generation was mated twice to produce the F3a and F3b offspring. F1a and F3b offspring were the only pups weaned directly to the test diets. Because of a high incidence of pup mortality, all other dams were given a control diet on the last expected day of gestation. Necropsy and microscopic examination were performed only on pups from the first mating of the F2 animals that died or were killed at weaning.

Until the F3 generation, body weights in parental males were 6-10% lower than control body weights. There were no significant treatment-related effects on mean litter size and the mean number of viable pups in each litter or on fertility or gestational indices. For all pups of the F1a generation, including controls, the number of pups weaned and the average body weight of those pups at weaning was reduced; however, greater reductions were seen in the test groups than in the control
group. The viability indices of the F3b pups receiving the test diet were reduced. The researchers stated the most remarkable result of the study was the reduced number of offspring surviving from day 5 until weaning; it was hypothesized that pups stopped nursing because they could taste the test article. A no-observed effect level (NOEL) for parental toxicity and effects on pups was not established; the NOEL for reproduction was 1%.

**GENOTOXICITY**

Refer to Table 1 for a summary of genotoxicity data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

**CARCINOGENICITY**

Effect on Colorectal Carcinogenesis

A group of 84 inbred male F344 rats was fed a diet containing 1% diethylhexyl sodium sulfosuccinate, and the control group was fed untreated feed. As part of a rodent model for colon carcinogenesis, rats of both groups were given a subcutaneous injection of 20 mg/kg bw of 1,2-dimethylhydrazine, once weekly for 20 wks. Twenty rats per group were killed after 3, 4, 5, and 6 mos. The test group tolerated the diethylhexyl sodium sulfosuccinate feed well. There was no statistically significant difference between the test and control group in the percentage of rats bearing tumors, and the number of tumors per rat increased progressively throughout the study. However, at 5 and 6 mos, each rat in the test group had fewer tumors of all histologic types (combined), at all organ sites, compared to controls; this difference was statistically significant for the duodenum, colon, rectum, and total number of gastrointestinal tumors at 5 mos.

**IRRITATION AND SENSITIZATION**

Dermal Irritation and Sensitization

**Non-Human**

Refer to Table 1 for a summary of non-human dermal irritation and sensitization data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

Occlusive patches containing 0.5 ml diethylhexyl sodium sulfosuccinate were applied to intact and abraded skin of six rabbits; the duration of exposure was not stated. For intact skin, the mean Draize scores for erythema and edema were 2.33 and 2.50, respectively, after 24 h and 1.66 and 1.0, respectively, after 72 h. For abraded skin the mean scores for erythema and edema were 2.50 and 2.50, respectively, after 24 h and 1.66 and 1.60, respectively, after 72 h.

**Human**

Refer to Table 1 for a summary of human dermal irritation and sensitization data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

Diethylhexyl sodium sulfosuccinate produced irritation, but it was not a sensitizer. For induction, a 15 mm occlusive patch containing 0.30 g of 2.5% ethylhexyl sodium sulfosuccinate in petrolatum was applied to the backs or forearms of 100 subjects; the patches were applied for 10 alternate 24-h periods. Challenge patches containing 0.30 g diethylhexyl sodium sulfosuccinate were applied to a previously untreated site on the back or forearm following a 7-day non-treatment period. The challenge sites were scored upon patch removal and 24 h later. During induction, the following observations were made: mild erythema in 11 subjects on days 3-10 and in 1 subject on days 3-7; mild erythema on all days except day 7 and intense erythema on day 7 in one subject; mild erythema on days 3-6/7 followed by intense erythema on days 6/7-10 in 6 subjects. No reactions were observed at challenge.

In a case report, a female subject had allergic contact dermatitis from diethylhexyl sodium sulfosuccinate that was an ingredient in a topical corticosteroid. In patch testing, the patient had a +++ reaction to 1% aq. diethylhexyl sodium sulfosuccinate on day 2 and day 4. The researchers noted that this was a rare reaction.

**Phototoxicity/Photoallergenicity**

**Human**

Refer to Table 1 for a summary of human phototoxicity data from the original safety assessment on diethylhexyl sodium sulfosuccinate.

**SUMMARY**

Diethylhexyl sodium sulfosuccinate (previously named dioctyl sodium sulfosuccinate), an anionic surfactant, was reviewed by the CIR Expert Panel in 1994, and the report was amended in 1998. In 1998, the Panel concluded that diethylhexyl sodium sulfosuccinate is safe as used in cosmetic formulations. Since the 1998 report was issued, the number of reported uses in cosmetic formulations has increased from 35 to 62 uses. However, the concentration of use has not changed. The data that were available for the 1998 report indicated that diethylhexyl sodium sulfosuccinate was used in a variety of product-types at concentrations of ≤5%; current information report that the maximum use concentration is 4.4% in eyebrow pencil formulations.
Metabolism and excretion studies have given mixed results on the primary route of excretion of diethylhexyl sodium sulfosuccinate; it does appear that diethylhexyl sodium sulfosuccinate is metabolized prior to excretion, and most of the dose is excreted within 24 h of dosing. In one oral study in rats, 66% of the radioactivity (labeled with $^{35}$S) was excreted in the feces and only 25-35% in urine, within 24-48 h after dosing. In other rat studies, with oral and i.v. administration, the majority of the radioactivity (radiolabel not specified) was excreted in the urine, rather than in the feces. Studies were also performed in rabbits and dogs in which diethylhexyl sodium sulfosuccinate was labeled with $^{14}$C, and again conflicting results were obtained. In rabbits, 87% and 69.7% of the radioactivity was excreted in the urine following oral and i.v. dosing, respectively; in dogs, approximately 70% of the radioactivity was excreted in the feces at 24-48 h after oral and i.v. dosing. Diethylhexyl sodium sulfosuccinate increased the penetration of curcumin and resveratrol, in vitro, through excised guinea pig and Yucatan micro-pig skin.

The dermal LD$_{50}$ of undiluted diethylhexyl sodium sulfosuccinate in rabbits was >10 g/kg; skin irritation was observed following the single dermal dose of 10 g/kg test material. The oral LD$_{50}$ was 2.64 g/kg bw in male albino ARS/ICR mice and approximately 0.65 g/kg bw in guinea pigs.

In repeated-dose oral studies in which rats were given feed containing 1% diethylhexyl sodium sulfosuccinate for 90 days or up to 1.5% for 26 wks, and in studies in which Beagle dogs were given tablets containing 30 mg/kg bw/day diethylhexyl sodium sulfosuccinate for 1 yr, no remarkable toxic effects were reported. In an inhalation study in rabbits, a 5-min exposure to 0.2% DSS, followed 30 min later by a 5 min exposure to 2% diethylhexyl sodium sulfosuccinate, greatly enhanced the alveolar absorption of $^{99m}$Tc-DTPA.

Diethylhexyl sodium sulfosuccinate was used as a positive control in a Draize ocular irritation study; 10% diethylhexyl sodium sulfosuccinate was severely irritating to rabbit eyes, inducing perforated damages.

Numerous studies examining the effect of the oral administration of diethylhexyl sodium sulfosuccinate, both dietary and by gavage, on the reproductive and developmental toxicity in rats were performed; one study was performed in mice. In a developmental study in mice and rats of a test substance containing 0.4% (w/v) diethylhexyl sodium sulfosuccinate, the NOAEL for maternal toxicity and teratogenic effects for both mice and rats was 400 mg/kg bw. In another developmental toxicity study in rats, the parental NOAEL was 400 mg/kg bw for a test substance containing 0.4% (w/v) diethylhexyl sodium sulfosuccinate. In a study in which gravid female Sprague-Dawley rats were fed a diet containing up to 2% diethylhexyl sodium sulfosuccinate, no adverse effects on maternal or fetal parameters were observed in the 1% test group, but in the 2% test group, significant incidences of resorptions and gross abnormalities, primarily exencephaly and, at times, spina bifida, anophthalmia, and associated skeletal defects, were reported. The NOAEL for maternal toxicity and teratogenic effects was 1%.

In a three-generation study in which rats were fed a diet containing up to 1% of a test substance containing 50% diethylhexyl sodium sulfosuccinate in aq. beverage-grade ethanol, a NOEL for parental toxicity and effects on pups was not established because of reduced body weight gains in the parents and reduced viability indices in the pups, but the NOEL for reproduction was 1%; the reduced viability index most likely was attributed to the pups discontinuing nursing because they could taste the test article.

In rats, a diet containing 1% diethylhexyl sodium sulfosuccinate did not have an effect on 1,2-dimethylhydrazine-induced colorectal carcinogenesis.

In clinical studies, 2.5% diethylhexyl sodium sulfosuccinate was an irritant, but not a sensitizer.

**DISCUSSION**

The Expert Panel determined that the existing safety assessment on diethylhexyl sodium sulfosuccinate should be expanded to include the seven dialkyl sulfosuccinate salts that are listed in the *International Cosmetic Ingredient Dictionary and Handbook*. Although data were not available on most of these additional ingredients, the Panel found the existing data on diethylhexyl sodium sulfosuccinate are sufficient to support the safety of this entire family of ingredients, stating that diethylhexyl sodium sulfosuccinate is a reasonable representative of all of the diesters. All of the diesters are of a similar alkyl chain length, all are symmetrically substituted-, and all have similar functions in cosmetic formulations. Additionally, these esters are not expected to be absorbed through the skin to any significant extent, and the reproductive effects observed in test animals orally exposed to diethylhexyl sodium sulfosuccinate are not likely effects of topical application of cosmetics containing these ingredients. Furthermore, there were no uses reported by which incidental ingestion would occur. Consistent with this view, the Panel noted that acute dermal toxicity of undiluted diethylhexyl sodium sulfosuccinate was quite low, with a dermal LD$_{50}$ of >10 g/kg in rabbits.
The Panel recognized that the dialkyl sulfosuccinate salts may enhance the penetration of other ingredients through the skin. The Panel cautioned that care should be taken in formulating cosmetic products that may contain these ingredients in combination with any ingredients whose safety was based on their lack of dermal absorption data, or when dermal absorption was a concern. In addition, the Panel confirmed its original discussion, acknowledging that under the exaggerated exposure conditions of the two repeated insult patch tests (RIPTs; continuous occlusive patch testing) presented in the original safety assessment of sodium diethylhexyl sulfosuccinate, the ingredient is a cumulative irritant, though not a sensitizer. The Panel recognized that a surfactant would most likely produce irritation under such conditions, and therefore, specified that products containing dialkyl sulfosuccinate salts must be formulated to be non-irritating.

Finally, the Panel discussed the issue of incidental inhalation exposure from hair sprays. The limited data available from short-term pharmaceutical studies in test animals exposed to diethylhexyl sodium sulfosuccinate aerosols suggest little potential for respiratory effects. This ingredient is reportedly used at concentrations up to 0.25% in cosmetic products that may be aerosolized. The Panel noted that 95% – 99% of droplets/particles would not be respirable to any appreciable amount. Furthermore, droplets/particles deposited in the nasopharyngeal or bronchial regions of the respiratory tract in these small amounts present no toxicological concerns based on the chemical properties and biological properties of this ingredient. Coupled with the small actual exposure in the breathing zone and the concentrations at which the ingredients are used, the available information indicates that incidental inhalation would not be a significant route of exposure that might lead to local respiratory or systemic effects. The Panel considered other data available to characterize the potential for the dialkyl sulfosuccinate salts to cause systemic toxicity, irritation, sensitization, reproductive and developmental toxicity, genotoxicity and carcinogenicity. They noted the lack of systemic toxicity in several acute and subchronic oral exposure studies, little or no irritation or sensitization in tests of dermal and ocular exposure, the absence of genotoxicity in Ames tests, and the lack of carcinogenicity in a subchronic oral exposure study. A detailed discussion and summary of the Panel’s approach to evaluating incidental inhalation exposures to ingredients in cosmetic products is available at http://www.cir-safety.org/cir-findings.

CONCLUSION

The CIR Expert Panel concluded that the following eight dialkyl sulfosuccinate salts are safe in the present practices of use and concentration in cosmetics described in this safety assessment when formulated to be non-irritating.

- Ammonium Dinonyl Sulfosuccinate*
- Diamyl Sodium Sulfosuccinate*
- Dicapryl Sodium Sulfosuccinate*
- Diethylhexyl Sodium Sulfosuccinate
- Diheptyl Sodium Sulfosuccinate*
- Dihexyl Sodium Sulfosuccinate*
- Diisobutyl Sodium Sulfosuccinate*
- Ditridecyl Sodium Sulfosuccinate*

*Not reported to be in current use. Were ingredients in this group not in current use to be used in the future, the expectation is that they would be used in product categories and at concentrations comparable to others in this group.
1. Ammonium Dinonyl Sulfosuccinate

2. Diamyl Sodium Sulfosuccinate

3. Dicapryl Sodium Sulfosuccinate

4. Diethylhexyl Sodium Sulfosuccinate

5. Diheptyl Sodium Sulfosuccinate
6. Dihexyl Sodium Sulfo succinate

7. Diisobutyl Sodium Sulfo succinate

8. Ditridecyl Sodium Sulfo succinate
TABLES

Table 1. Data from the previous review of diethylhexyl sodium sulfosuccinate

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Summary data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Method of Manufacture</td>
<td>Maleic anhydride is reacted with 2-ethylhexanol to product bis(2-ethylhexyl)maleate, which is then combined with sodium bisulfite under conditions conducive to the formation of the sulfonate structure through rearrangement with an accompanying saturation of the olefinic bond</td>
</tr>
<tr>
<td>Single-Dose Toxicity - Oral</td>
<td>The oral LD₅₀ in rats of a product containing 84% diethylhexyl sodium sulfosuccinate was 3.69 g/kg, and the LD₅₀ of a commercially available diethylhexyl sodium sulfosuccinate, administered as a 10% aq. solution or as an emulsion, was 1.9 g/kg in female rats. In mice, the oral LD₅₀ for a commercial product containing an unspecified amount of diethylhexyl sodium sulfosuccinate as the active ingredient was 4.8 g/kg, and the i.v. LD₅₀ for the product was 0.06 g/kg.</td>
</tr>
<tr>
<td>Repeated Dose Toxicity - Dermal</td>
<td>Four mL/kg of a test article containing an effective dose of 0.00126% diethylhexyl sodium sulfosuccinate in formulation was applied to the backs of rats, 5 days/wk, for 67 wks. (It is not stated whether the applications were covered.) No remarkable toxic effects were noted. However, minimal to moderate skin irritation was observed sporadically throughout the study.</td>
</tr>
<tr>
<td>Repeated Dose Toxicity - Oral</td>
<td>Repeated dose oral toxicity studies were performed in the 1940s on diethylhexyl sodium sulfosuccinate in rats, dogs, and monkeys. No remarkable toxic effects were found in rats fed ≤1.25 g/kg bw for 24 wks, in dogs fed 0.10 or 0.25 g/kg bw of a commercial surfactant containing diethylhexyl sodium sulfosuccinate as the active ingredient for 24 wks, or in monkeys fed 0.125 g/kg of the same preparation for 24 wks. However, in a study in which male rats were fed 2, 4, or 8% diethylhexyl sodium sulfosuccinate for 4 mos, the researchers found these doses to be very toxic. Reduced body weight gains were reported in rats fed ≤1% diethylhexyl sodium sulfosuccinate for 2 yrs.</td>
</tr>
<tr>
<td>Repeated Dose Toxicity - Inhalation</td>
<td>Rats exposed to an aerosol of a product containing an effective diethylhexyl sodium sulfosuccinate concentration of 0.21% at an exposure concentration of 4.2 mg/m³, 4 h/day, 5 days/wk, for 13 wks, had significant changes in hematology and clinical chemistry parameters as compared to controls. Mongrel dogs were exposed for 30–45 min to a 1% solution of a commercial detergent containing diethylhexyl sodium sulfosuccinate in equal volumes of 95% ethanol and isotonic saline, at a final concentration of 15 mg/kg of the test material, and then killed 30 min, 2 h, or 4 h after exposure. Gross, but not microscopic changes in pulmonary structure and changes in pulmonary function were observed; the researchers suggested that the test article was capable of displacing the normal alveolar surfactant into the airway and resulted in increased alveolar surface tension and instability.</td>
</tr>
<tr>
<td>Ocular Irritation</td>
<td>In the eyes of rabbits, concentrations of ≥25% diethylhexyl sodium sulfosuccinate were severely irritating, and concentrations of ≤10% produced little or no irritation.</td>
</tr>
<tr>
<td>Reproductive and Developmental Toxicity</td>
<td>In a three-generation study, rats were fed 0, 0.1, 0.5, or 1.0% diethylhexyl sodium sulfosuccinate. Body weights of all parental males and in F₁ and F₂ females of the 0.5 and 1.0% test groups were decreased, and the body weights of pups of all three generations were decreased compared to controls. No effects on reproductive parameters, and no gross lesions or treatment-related mortalities, were observed.</td>
</tr>
<tr>
<td>Genotoxicity</td>
<td>Diethylhexyl sodium sulfosuccinate was not mutagenic in an Ames test, but with metabolic activation, it did induce chromosomal aberrations in Chinese hamster ovary cells at treatment doses close to threshold toxicity.</td>
</tr>
<tr>
<td>Dermal Irritation and Sensitization – Non-Human</td>
<td>In rabbits, a 24-h patch of 2% diethylhexyl sodium sulfosuccinate resulted in an irritation score of 3.7/8 for intact skin and 1.7/8 for abraded skin. In a single-insult occlusive patch test, a 10% solution of a product containing 84% diethylhexyl sodium sulfosuccinate in propylene glycol was minimally irritating to rabbit skin. In a 2-wk study, 10 applications of 1% diethylhexyl sodium sulfosuccinate to intact abdominal skin in rabbits resulted in moderate hyperemia; test concentrations of 5% produced a burn from two to four 24-h applications and of 25% produced a burn with one 24-h application. Application of 5, 10, and 15% diethylhexyl sodium sulfosuccinate to abraded rabbit abdominal skin for 3 days was moderately to severely irritating. In a study examining acanthosis following repeated (number not stated) dermal applications of 2, 10, and 20% diethylhexyl sodium sulfosuccinate, an acanthosis factor (AF) was calculated from the difference in epidermal thickness, with 1 unit being equivalent to 2.7 μm. The AFs were 1.8, 2.5, and 3.3, respectively.</td>
</tr>
<tr>
<td>Dermal Irritation and Sensitization – Human</td>
<td>In a 50-subject study, a single 24-h occlusive patch of a formulation containing 2.5% diethylhexyl sodium sulfosuccinate was not an irritant. In mini-cumulative irritancy tests, the primary irritation index (PII) of four products containing a 3.5% solution of 84% diethylhexyl sodium sulfosuccinate ranges from 0.25 – 0.80; the PII of two products containing a 0.25% solution of 84% diethylhexyl sodium sulfosuccinate were 1.78 and 1.85; and the PII of a product containing a 0.1% solution of 84% diethylhexyl sodium sulfosuccinate was 0.04. In a 21-day cumulative irritancy test of a product containing 1.13% solution of diethylhexyl sodium sulfosuccinate performed in 7 volunteers, the total irritation score was 324/578 for all seven subjects over the 21-day period; the average score per panelist was 46.3/84. In a 110-subject human repeated insult patch test (HRRIPT) of 1, 3, and 5% diethylhexyl sodium sulfosuccinate and a 107-subject HRRIPT of a 50/50 dilution in distilled water of an eyebrow pencil containing 2.5% diethylhexyl sodium sulfosuccinate, reactions were observed during induction, but not at challenge. In a number of additional HRRIPTs with 0.21 or 0.42% diethylhexyl sodium sulfosuccinate or with a product containing 0.1% diethylhexyl sodium sulfosuccinate (84% pure), no reactions were observed during induction.</td>
</tr>
<tr>
<td>Photoallergenicity</td>
<td>In a study investigating the photocontact allergenic potential of a product containing 0.25% diethylhexyl sodium sulfosuccinate in 25 subjects, there were no reactions during the induction or the challenge phase that were attributable to ethylhexyl sodium sulfosuccinate.</td>
</tr>
</tbody>
</table>
Table 2. Data on constituent alcohols

**Caprylic Alcohol**
- Dermal Irritation – Non-Human: caprylic alcohol applied full strength to intact or abraded rabbit skin produced a mild irritation.
- Dermal Irritation and Sensitization – Human: tested in at a concentration of 2% in petrolatum, caprylic alcohol produced no irritation in a 48 h closed-patch test in 25 human subjects.

**Isobutyl Alcohol**
- Repeated Dose Toxicity - Inhalation: rats (10/sex/group) were exposed via inhalation to isobutyl alcohol vapor concentrations of approximately 0, 770, 3100, or 7700 mg/m³, for 6 h/day, 5 days/week, for 14 weeks; the functional observational battery was conducted along with endpoints of motor activity, neurophysiology, and scheduled-controlled operant behavior; a slight reduction in responsiveness to external stimuli was observed in all treated groups during exposure; this effect resolved upon cessation of exposure to isobutyl alcohol.

**Ethylhexyl Alcohol**
- Toxicokinetics: in vitro dermal absorption rates were determined for ethylhexyl alcohol in rats and humans; in rats, the rate was 0.22 mg/cm²/h and in the human it was 0.038 mg/cm²/h; accordingly, the human rate of ethylhexyl alcohol absorption was 5.78 times slower than the rate in the rat.
- Dermal Toxicity: in three different acute dermal toxicity studies on rabbits with ethylhexyl alcohol, the LD₅₀ values reported were 2380, >2600 and >5000 mg/kg bw; 10 rats were dosed with 2 ml/kg bw/day (1600mg/kg/day) via single application on shaved backs; absolute and relative thymus wts, liver granulomas, bronchiectasis in the lung, renal tubular epithelial necroses, edematous heart and testes, and spermatogenesis, all decreased; 10 rats/sex were dosed with 0, 500, or 1000 mg/kg bw/day (5 days occlusive, 2 days untreated, 4 days treated); 500 and 1000 mg treated rats exhibited minimal exfoliation, decreased spleen wt and increased serum triglycerides in females.
- Ocular Irritation: instillation of 20 μg of ethylhexyl alcohol into the conjunctival sac of rabbits caused moderately severe irritation of the cornea.

**Caprylic Alcohol**
- Dermal Irritation – Non-Human: ethylhexyl alcohol was applied under occlusion to the skin of 3 male rabbits for 4 hours and found to be irritating; in another study with rabbits, 0.5 ml of ethylhexyl alcohol was applied under occlusion on intact skin for 1, 2, 4, and 24 hours; irritation was considered high, and effects seen after 7 days were not reversible.
- Dermal Irritation and Sensitization - Human: tested at a concentration of 4% in petrolatum, ethylhexyl alcohol produced no irritation in a 48 h occlusive-patch test in 29 male volunteers; in a maximization study, ethylhexyl alcohol did not induce any sensitization reactions.
- Reproductive and Developmental Toxicity: a group of female rats was exposed for 7 h/day to 850 mg/m³ of ethylhexyl alcohol on gestation days 1-19; dams were sacrificed at day 20; ethylhexyl alcohol reduced maternal feed intake, but did not produce any malformations; the estrogenic activity of 2-ethylhexanoic acid was examined using an E-SCREEN assay using T47D human breast cancer cells; weak estrogenic activity was observed; additional details were not provided.

**Genotoxicity**: in vitro, ethylhexyl alcohol was negative in a number of Ames assays, a liquid suspension assay, mouse lymphoma assay, and unscheduled DNA synthesis assay; in a ³H-thymidine assay, there was a dose-dependent inhibition of ³H-thymidine into replicating DNA, with a dose-dependent increase in the ratio of acid-soluble DNA incorporated into the thymidine; the urine of rats dosed orally with 1000 mg/kg bw ethylhexyl alcohol was not mutagenic; in vivo, ethylhexyl alcohol was not genotoxic in a mouse micronucleus test or a transformation assay.

**Carcinogenicity**: B6C3F₁; mice (50/sex/group) were administered 0, 50, 200, or 750 mg/kg bw/day via gavage, 5 days/week for 18 mos; at the 750 mg/kg dose, weak hepatocellular carcinoma increased in females, bw gain decreased and mortality increased; F344 rats (50/sex/group) were administered 0, 50, 150, or 500 mg/kg bw/day via gavage, 5 days/week for 24 mos; rats dosed ≥150 mg/kg were characterized with bw gain decrease, lethargy and unkemptness; at 500 mg/kg, mortality in females was at 52%.
