Safety Assessment of *Ginkgo biloba*-Derived Ingredients as Used in Cosmetics

Status: Tentative Report for Public Comment
Release Date: March 16, 2018
Panel Meeting Date: June 4-5, 2018

All interested persons are provided 60 days from the above date to comment on this safety assessment and to identify additional published data that should be included or provide unpublished data which can be made public and included. Information may be submitted without identifying the source or the trade name of the cosmetic product containing the ingredient. All unpublished data submitted to CIR will be discussed in open meetings, will be available at the CIR office for review by any interested party and may be cited in a peer-reviewed scientific journal. Please submit data, comments, or requests to the CIR Executive Director, Dr. Bart Heldreth.

The 2018 Cosmetic Ingredient Review Expert Panel members are: Chairman, Wilma F. Bergfeld, M.D., F.A.C.P.; Donald V. Belsito, M.D.; Curtis D. Klaassen, Ph.D.; Daniel C. Liebler, Ph.D.; Ronald A. Hill, Ph.D. James G. Marks, Jr., M.D.; Ronald C. Shank, Ph.D.; Thomas J. Slaga, Ph.D.; and Paul W. Snyder, D.V.M., Ph.D. The CIR Executive Director is Bart Heldreth, Ph.D. This safety assessment was prepared by Christina L. Burnett, Senior Scientific Analyst/Writer.
ABSTRACT
The Cosmetic Ingredient Review (CIR) Expert Panel (Panel) assessed the safety of 10 Ginkgo biloba-derived ingredients, which are most frequently reported to function in cosmetics as skin conditioning agents or antioxidants. The Panel reviewed the available data to determine the safety of these ingredients. The Panel concluded that the data are insufficient to determine the safety of these ingredients.

INTRODUCTION
Most of the Ginkgo biloba-derived ingredients detailed in this safety assessment are reported to function as skin conditioning agents, while some are reported to function as antioxidants in cosmetics, according to the web-based International Cosmetic Ingredient Dictionary and Handbook (wINCI; Dictionary; see Table 1).1 Reported functions of Ginkgo Leaf Terpenoids include antioacne agent, antifungal agent, and external analgesic. These functions are not considered cosmetic functions in the United States and, therefore, do not fall under the purview of CIR. This assessment of the safety of the following 10 Ginkgo biloba-derived ingredients is based on the data contained in this report:

- Ginkgo Biloba Leaf Extract
- Ginkgo Biflavones
- Ginkgo Biloba Leaf
- Ginkgo Biloba Leaf Cell Extract
- Ginkgo Biloba Leaf Powder
- Ginkgo Biloba Leaf Water
- Ginkgo Biloba Meristem Cell
- Ginkgo Biloba Nut Extract
- Ginkgo Biloba Root Extract
- Ginkgo Leaf Terpenoids

Ginkgo biloba leaves and nuts (also called seeds) have been used as a source of traditional Chinese medicines.2 More recently, extracts of the leaves of Ginkgo biloba have been used as herbal medicines or dietary supplements in the treatment of heart disease, eye ailments, tinnitus, cerebral and peripheral vascular insufficiency, injuries involving brain trauma, demetias, short-term memory improvement, cognitive disorders secondary to depression, vertigo, and various other cognitive disorders.2,3 Investigations into the efficacy of the leaf extract for these uses are numerous and are mainly based on oral administration of supplements. However, there are no publically available toxicity data that corresponds to specific use of these ingredients as cosmetics. The focus of this safety assessment will be on data relevant to the use of Ginkgo biloba-derived ingredients in cosmetics, with specific focus on dermal application when available.

Because often in the published literature the information provided is not sufficient to determine how well the tested substance represents the cosmetic ingredient, the taxonomic name is used unless it is clear that the test substance is similar to a cosmetic ingredient. However, in the case of data on the extract of Ginkgo biloba leaves, the abbreviation GBE will be used, unless the data specifically are related to the cosmetic use of Ginkgo Biloba Leaf Extract.

Botanicals, such as Ginkgo biloba-derived ingredients, may contain hundreds of constituents, some of which may have the potential to cause toxic effects. In this assessment, CIR is reviewing the potential toxicity of each of the Ginkgo biloba-derived ingredients as a whole, complex mixture. CIR is not reviewing the potential toxicity of the individual constituents, except wherein such constituents are also ingredients under review.

This safety assessment includes relevant published and unpublished data for each endpoint that is evaluated. Published data are identified by conducting an exhaustive search of the world’s literature. A listing of the search engines and websites that are used and the sources that are typically explored, as well as the endpoints that CIR typically evaluates, is provided on the CIR website (http://www.cir-safety.org/supplementaldoc/preliminary-search-engines-and-websites; http://www.cir-safety.org/supplementaldoc/cir-report-format-outline). Unpublished data are provided by the cosmetics industry, as well as by other interested parties.

CHEMISTRY
Definition and Plant Identification
The definitions and functions of the Ginkgo biloba-derived ingredients included in this report are provided in Table 1. The raw materials for the ingredients in this report are obtained from the deciduous tree, Ginkgo biloba, which has fan-shaped leaves that turn golden yellow in autumn and which can grow to 40 m (~131 ft) tall.2 The female trees bear offensive-smelling, inedible fruit that contain a single thin-shelled semi-edible nut. Ginkgo trees are planted widely as ornamental trees via cultivation. Few naturally-occurring specimens grow in Zhejiang province China. Trees grown commercially for the leaves are found in China, France, and in the United States.

Physical Properties
Product specifications for Ginkgo Biloba Leaf Extract (prepared in water) and Ginkgo Biloba Nut Extract (prepared in glycerin) reported by a supplier are described in Table 2.
Methods of Manufacturing

Ginkgo Biloba Leaf Extract

A general description of manufacturing for “medicinal” GBE reported that the leaves of the Ginkgo biloba tree are harvested either mechanically or by hand from plantations or in the wild. The leaves are then dried and pressed into balls. A dry extract from the dried leaf of Ginkgo biloba can be manufactured using acetone/water and subsequent purification steps without addition of concentrates or isolated ingredients.

GBEs may be full extracts or standardized extracts. Full extracts are prepared with alcohol and contain all constituents soluble in alcohol. Standardized extracts (one of which is referred to as EGb 761 in published literature) are more common, especially in herbal supplements, and are prepared in manufacturer-dependent multi-step processes (Scheme 1). These processes may include additional steps in which some compounds, such as flavonoids and lactones, are enriched while others, such as ginkgolic acids, are removed.

![Scheme 1. General manufacturing process of a standardized Ginkgo biloba leaf extract (EGb 761)](image)

A manufacturer has reported that one Ginkgo Biloba Leaf Extract product is produced through extraction with an ethanol-water solution, while another product is produced through extraction with an ethanol-water solution before being evaporated and resolved in 50% butylene glycol.

Ginkgo Biloba Meristem Cell

Ginkgo Biloba Meristem Cell is produced by sterilizing cambium-containing tissue from the Ginkgo biloba plant, isolating the cambial meristem cells from the tissue, and then culturing the cells for proliferation. The cultured cambial meristem cells are then subjected to specific culture conditions (details not provided) in order to produce various secondary metabolites. Finally the cultured cambial meristem cells are harvested with a filter-press.

Composition/Impurities

Ginkgo Biloba Leaf Extract

Table 3 summarizes the composition ranges of the major constituents of various extracts (standardized and non-standardized) of Ginkgo biloba leaves.

The target levels of the major constituents of the standardized GBE EGb 761 are reported to be: not less than 6% total terpene trilactone content, not less than 24% total flavonol glycosides, and not more than 5 ppm (0.0005%) ginkgolic acids. This extract is reported to be a brown powder with characteristic smell containing not more than 20 ppm heavy metals and not more than 2 ppm arsenic. The standardized extract used in National Toxicology Program (NTP) studies is reported to contain 15.4% terpene trilactones, 31.2% flavonol glycosides, and 10.45 ppm (0.001%) ginkgolic acids.
According to an analysis of crude extracts of *Ginkgo biloba* leaves, there are seasonal differences in the levels of certain constituents, with concentrations of flavonol glycosides higher in the spring than in the autumn (136.3 mg/100 g versus 46.0 mg/100 g) and biflavones higher in the autumn than in the spring (194.8 mg/100 g versus 44.28 mg/100 g). General *Ginkgo biloba* composition was reported in the *Physician's Desk Reference for Herbal Medicines* to be the following: flavonoids (0.5% to 1.8%) including monosides, biosides and triosides of quercetin, isorhamnetins, 3-O-methylmyristicin, and kaempferol; bilflavonoids (0.4% to 1.9%) including amentoflavone, bilobetin, 5-methoxybilobetin, ginkgetin, and isoginkgetin; pranthocyanidins (8% to 12%); trilactonic diterpenes (0.06% to 0.23%) including ginkgolide A, B, and C; and trilactonic sesquiterpene bilobalide (0.04% to 0.2%).

The *United States Pharmacopeia* states that “ginkgo” consists of the dried leaf of *Ginkgo biloba* Linne (Fam. Ginkgoaceae). It contains not less than 0.5% of flavonoids, calculated as flavonol glycosides, with a mean molecular mass of 756.7; and not less than 0.1% of terpene lactones, calculated as the sum of bilobalide, ginkgolide A, ginkgolide B, and ginkgolide C, both on the dried basis. This reference also states that “powdered ginkgo extract” is prepared from dried and comminuted leaves of *Ginkgo* extracted with an acetone-water mixture or other suitable solvents. It contains not less than 22.0% and not more than 27.0% of flavonoids, calculated as flavonol glycosides, with a mean molecular mass of 756.7; and not less than 5.4% and not more than 12.0% of terpene lactones, consisting of between 2.6% and 5.8% of bilobalide and between 2.8% and 6.2% of ginkgolide A, ginkgolide B, and ginkgolide C.

The *British Pharmacopoeia* states that “ginkgo leaf” content should be not less than 0.5% of flavonoids, calculated as flavone glycosides (dried drug). An extraction with 60% w/w ethanol of dried green *Ginkgo biloba* leaves yielded an extract comprised of 3.4% flavone glycosides, 0.7% terpene lactones, and 5.5% ginkgolic acids. Further fractionation by liquid-liquid partition between water and heptane yielded a fraction containing 0.3% flavone glycosides, 0.1% terpene lactones, and 24.6% ginkgolic acids.

For use as an herbal medicine in Germany, GBE must be extracted with acetone/water and contain 22%-27% flavone glycosides (quercetin and kaempferol) with a molar mass of 756.7 (quercetin glycoside) and 740.7 (kaempferol glycoside); 5%-7% terpene lactones of which 2.8%-3.4% consists of ginkgolides A, B, and C and 2.6%-3.2% bilobalide; and not less than 5 ppm ginkgolic acid, 0.1 mg free quercetin, 0.2 mg free kaempferol, and less than 20 ppm heavy metals.

A manufacturer has reported that *Ginkgo Biloba Leaf Extract* produced with ethanol/water and sold in butylene glycol contains 0.51% flavonol glycosides, 0.16% terpene lactones (0.08% bilobalide, 0.04% ginkgolide A, 0.02% ginkgolide B, and 0.02% ginkgolide C), 0.21% quercetin, and less than 0.1 ppm ginkgolic acid.

A certificate of analysis on a Ginkgo Biloba Leaf Extract (solvent not specified) described the sample as a light tan powder that contained 25.3% ginkgo flavonol, 6.4% ginkgolides (bilobalide, ginkgolide A, ginkgolide B, ginkgolide C), 2.3 ppm ginkgolic acid, 0.1 mg free quercetin, 0.2 mg free kaempferol, and less than 20 ppm heavy metals.

A supplier for a Ginkgo Biloba Leaf Extract in an alcohol base reported that heavy metals were below reporting limits and no residual pesticides were detected. This supplier also reported the 26 allergens defined by the 7th amendment to the EU Cosmetic Directive were below testing thresholds.

**Ginkgo Biloba Meristem Cell**

A supplier has reported that Ginkgo Biloba Meristem Cell is distinctly different from general GBEs, with major constituents being catechin, galloatechecin, epigallocatechin, and bilobalide.

**UV Absorption**

In a spectral analysis provided by a supplier of a Ginkgo Biloba Leaf Extract (ethanol: water:butylene glycol extract), no maximum UV absorption peaks were observed in the 280 to 450 nm range.

**USE**

**Cosmetic**

The safety of the cosmetic ingredients included in this assessment is evaluated based on data received from the U.S. Food and Drug Administration (FDA) and the cosmetics industry on the expected use of these ingredients in cosmetics. Use frequencies of individual ingredients in cosmetics are collected from manufacturers and reported by cosmetic product category in the FDA Voluntary Cosmetic Registration Program (VCRP) database. Use concentration data are submitted by the cosmetics industry in response to surveys, conducted by the Personal Care Products Council (Council), of maximum reported use concentrations by product category.
According to 2017 VCRP survey data, Ginkgo Biloba Leaf Extract has the most reported uses in cosmetic products, with a total of 726; the majority of the uses are in leave-on eye makeup preparations and skin care products (Table 4).20 Two other Ginkgo-derived ingredients are reported to be in use, with 24 or fewer uses reported in the VCRP. However, the results of the concentration of use survey on these 10 ingredients conducted in 2014 by the Council indicate use for only Ginkgo Biloba Leaf Extract, at a maximum of 1%, as reported in face and neck skin preparations.21 A concentration of use survey has not yet been completed for Ginkgo Biloba Leaf Cell Extract. Ingredients with no reported uses in the VCRP or by the Council are listed in Table 5.

Ginkgo Biloba Leaf Extract may be used in products that can be incidentally ingested or come into contact with mucous membranes; for example, use is reported in a lipstick at up to 0.2%.20,21 Additionally, Ginkgo Biloba Leaf Extract has been reported to be used in products that may come into contact with the eyes, such as eye shadows and eye lotions at up to 0.01%.20,21 Moreover, Ginkgo Biloba Leaf Extract was reported to be used in spray products that could possibly be inhaled, like pump spray suntan products at a maximum concentration of 0.05%.21 In practice, 95% to 99% of the droplets/particles released from cosmetic sprays have aerodynamic equivalent diameters > 10 µm, with propellant sprays yielding a greater fraction of droplets/particles below 10 µm compared with pump spray.22-25 Therefore, most droplets/particles incidentally inhaled from cosmetic sprays would be deposited in the nasopharyngeal and bronchial regions and would not be respirable (i.e., they would not enter the lungs) to any appreciable amount.22,24 Ginkgo Biloba Leaf Extract is also used in powders, and these products could possibly be inhaled; for example, it is used in face powders at a maximum concentration of 0.05%. Conservative estimates of inhalation exposures to respirable particles during the use of loose powder cosmetic products are 400-fold to 1000-fold less than protective regulatory and guidance limits for inert airborne respirable particles in the workplace.26-28

The Ginkgo biloba-derived ingredients described in this report are not restricted from use in any way under the rules governing cosmetic products in the European Union.29

Non-Cosmetic

GBE is used extensively as an herbal supplement for anti-inflammatory, cognitive-promoting, antioxidant, and vascular effects at daily doses of 120 to 240 mg.23,30 In Germany, GBE is an approved herbal medicine for use for treatment of memory deficits, dementia, and other organic brain syndromes when extracted with acetone/water.13 It is not approved when extracted with other solvents due to lack of supporting safety data.

Standardized GBEs and/or constituents of the extracts, such as bilobalide, kaempferol and ginkgetin, have also been studied for potential neuroprotective effects against Huntington’s disease, and for anti-inflammatory and analgesic effects on post-surgical incisions. Additionally, these extracts have been researched for their effects on diseases such as osteoarthritis and atopic dermatitis, for protective effects (antioxidant) against radiation and chemotherapy-induced toxicity, for anticancer effects, and for therapy for vitiligo.31-39

GBE as an herbal supplement may interact with pharmaceutical drugs and act as or enhance anticoagulants, anti-inflammatory agents, antihypertensives, and/or anesthetics which may lead to hemorrhage, apraxia, hematoma, hyphema, permanent neurological deficit, and death.40,41 The Physician’s Desk Reference for Herbal Medicines reports major drug interaction risks with anticoagulants, nonsteroidal anti-inflammatory drugs (NSAIDs), and trazodone and moderate drug interaction risks with low molecular weight heparins and thrombolytic agents.5 GBE may also interact with anticonvulsants, buspirone, insulin, monoamine oxidase (MAO) inhibitors, nicardipine, nifedipine, omeprazole, papaverine, St. John’s wort, selective serotonin reuptake inhibitors, and thiazide diuretics.

The nuts of Ginkgo biloba are a delicacy in Japan and China, but must be removed completely from the pulp, boiled or roasted, and eaten sparingly (limit 8 - 10 per day).2 In traditional Chinese medicine, the nut is dried and used to treat such ailments as asthma, cough, bronchitis, scabies, and sores.

TOXICOKINETICS

In general, toxicokinetics data are not expected to be found on botanical ingredient because each botanical ingredient is a complex mixture of hundreds of constituents. However, there have been many pharmacokinetics studies on GBEs, specifically on some of the key constituents, which indicate GBE may be well absorbed after oral administration.8

Dermal Penetration

The ability of the GBE constituent, quercetin, to penetrate the skin while in a cosmetic formulation was studied in vitro with human dermatomed skin.42 The cosmetic formulation used in the study was an emulsion containing trilaureth-4 phosphate, ammonium acryloyldimethyltaurate/VP copolymer and emollients, sclerotium gum, humectants, preservatives, and water that was prepared and supplemented with 6.0% (w/w) triturated Ginkgo biloba glycolic leaf extract. An analysis of the GBE used in this study showed it contained 0.12% quercetin. The test formulation (10 mg/cm²) was applied to the skin samples (n = 6) that were mounted on Franz diffusion cells for 24 h. Samples of the receptor fluid (citrate buffer with 0.5% polysorbate 20; pH 5.5) were taken after 6 h and 24 h exposures and quantified with high performance liquid chromatography (HPLC). The skin cells were washed at the end of the exposure time and the stratum corneum was removed by tape stripping. The stratum corneum and viable epidermis contained 0.17 ± 0.002 µg/cm² (24% of the applied dose) and 0.23 ±
0.04 µg/cm² (33% of the applied dose) quercetin, respectively. Quercetin in the dermis and the receptor fluid was below limits of quantification or below limits of detection. Approximately 40% quercetin was measured in the washing solution. The total recovery of quercetin was approximately 97%.

**Absorption, Distribution, Metabolism, and Excretion (ADME)**

**Animal**

The absorption, distribution, and elimination of a radiolabeled GBE were studied in male and female Sprague-Dawley rats. The rats received a single oral suspended dose (20 µCi; 380 mg/kg) of a radiolabeled GBE. The test material was obtained from *Ginkgo biloba* grown under a supply of [14C]-acetate. Analysis showed that the flavonol glycosides and proanthocyanidins bore the radiolabel; no radioactivity was detected in the terpenes or the main sugars after the hydrolysis of glycosides. The pharmacokinetic results, based on blood specific activity data versus time course, were characteristic of a two-compartment model with an apparent first order phase and a half-life of approximately 4.5 h. Expired [14C]-CO₂ represented 16% of the administered dose 3 h post-treatment. After 72 h, 38% of the radioactivity was excreted via exhalation, while 21% was determined to be excreted in the urine and 29% was excreted in the feces. The researchers of this study concluded that at least 60% of the radiolabeled GBE was absorbed. The site of absorption was likely the upper gastrointestinal tract.

**Human**

The bioavailability and pharmacokinetics of *Ginkgo biloba* L. in a human plasma study was investigated using 3 different preparations. The preparations were a tincture of fresh *Ginkgo biloba* leaves (extracted with 65% v/v ethanol; 1 ml contains 920 mg *Ginkgo biloba* leaves as active ingredient), *Ginkgo biloba* fresh plant extract tablets (extracted with 67% v/v ethanol; one 250 mg tablet contains 90 mg fresh plant extract), and *Ginkgo biloba* extract EGb 761® tablets (extracted with 60% m/m acetone; one tablet contains 40 mg purified dried extract). The study was performed on 24 healthy volunteers (6 males and 18 females): each volunteer received a single oral dose of the maximum registered daily dosage of either the tincture (90 drops or 2.73 ml), the fresh plant extract (4 tablets), or EGb 761® (3 tablets) with 100 ml. Prior to dosing, each preparation was analyzed for concentrations of bilobalide (646.93 µg, 1974.96 µg, and 3672.39 µg for the tincture, fresh plant extract, and EGb 761®, respectively), ginkgolide A (298.14 µg, 881.52 µg, and 1571.37 µg for the tincture, fresh plant extract, and EGb 761®, respectively), and ginkgolide B (147.45 µg, 524.56 µg, and 836.46 µg for the tincture, fresh plant extract, and EGb 761®, respectively) prior to the plasma study with liquid chromatography-mass spectrometry (LC-MS). Blood samples (36 ml) were taken 30 min prior to administration and 15, 30, 45, 60, and 360 min after administration. The samples were centrifuged to separate the plasma and plasma was analyzed by LC-MS. The resulting maximum concentrations (median) of bilobalide, ginkgolide A and ginkgolide B in plasma after administration of the maximum daily dose of the different *Ginkgo biloba* products were as follows: 3.53, 3.62, and 1.38 ng/mL, respectively, after administration of the tincture; 11.68, 7.36, and 4.18 ng/mL, respectively, after administration of the fresh plant extract tablets; and 26.85, 16.44, 9.99 ng/mL, respectively, after administration of EGb 761® tablets. The authors of study concluded that ginkgolide A and B and bilobalide are bioavailable after oral dosing of 3 different *Ginkgo biloba* preparations.

**TOXICOLOGICAL STUDIES**

**Ginkgo Biloba Leaf Extract**

**Oral**

The LD₅₀ of a standardized GBE (EGb 761®) administered orally to mice was reported to be 7730 mg/kg.

**Intravenous**

The LD₅₀ after intravenous administration of a standardized GBE (EGb 761®) was 1100 mg/kg for both rats and mice.

**Ginkgo Biloba Meristem Cell**

**Oral**

In a toxicity test to determine lethal dose, a single oral dose of 0 or 2000 mg/kg Ginkgo Biloba Meristem Cell was administered to 5 male and female Sprague-Dawley rats in each group (written as provided, no further details). After a 14 day observation period, the animals were killed and underwent necropsy. No unscheduled deaths or treatment-related effects were observed during the observation period or at necropsy. The lethal dose for Ginkgo Biloba Meristem Cell was greater than 2000 mg/kg in this rat study.

In a single dose oral volume increase toxicity test, 2 male and female Beagle dogs (written as provided, no further details) received Ginkgo Biloba Meristem Cell at 250, 500, and 1000 mg/kg, respectively, for 4 days. No unscheduled deaths were observed. All animals vomited after receiving 500 and 1000 mg/kg of the test material. Only 1 animal vomited...
after receiving the 250 mg/kg dose, but the effects were determined to be too slight a symptom to confirm treatment-related effects. No adverse effects were observed in body weights or at necropsy. The maximum tolerated dose for Ginkgo Biloba Meristem Cell was determined to be greater than 1000 mg/kg in this dog study.

Short-Term Studies

Ginkgo Biloba Leaf Extract
Oral

The results of a combined liver comet assay (see Genotoxicity section) using male and female C3H-derived constitutive androstane receptor knockout (CARKO) and wild-type mice found no abnormal clinical signs and no treatment-related effects on body weight following oral exposure of up to 2000 mg/kg body weight/day of a GBE used by the NTP for 3 days in either mouse genotype. Relatively liver weights were significantly increased in male and female wild-type mice at all doses of a GBE in a dose-dependent manner. The liver weights in the CARKO mice were similar to the negative control group. The wild-type mice in all GBE-treated groups had dose-dependent slight-to-moderate hepatocellular hypertrophy in the centrilobular area; this effect was only observed in a single CARKO mouse in the highest dose group. No histopathological findings suggesting cytotoxicity in the liver was observed in any GBE-treated groups.

Ginkgo Biloba Meristem Cell
Oral

In a dose-range finding study for a 13-week oral repeated dose toxicity test (see below), groups of male and female Sprague-Dawley rats received 500, 1000, or 2000 mg/kg Ginkgo Biloba Meristem Cell for 4 weeks (number of rats/group and route of administration not described). No unscheduled deaths or clinical signs of toxicity were observed during the treatment period. Additionally, no treatment-related changes in body weight gains, feed intake, hematological/biochemical measurements, or organ weights were observed. No adverse effects were noted at necropsy in any dose group.

Subchronic Toxicity Studies

Ginkgo Biloba Leaf Extract
Oral

The toxicity of a particular GBE was investigated in a 3-month mouse study performed by the NTP. Groups of 10 male and 10 female B6C3F1/N mice received 0, 125, 250, 500, 1000, or 2000 mg/kg body weight of the GBE in corn oil via gavage, 5 days per week for 14 weeks. Control groups received corn oil (5 ml/kg). Clinical findings and body weights were recorded initially, then weekly, and at the end of the study. Blood was collected at the end of the study from all animals for hematological analyses. Sperm motility and vaginal cytology evaluations were made on the mice in the 0, 500, 1000, and 2000 mg/kg dose groups. At the end of the study period, tissues from over 40 sites were examined for every animal, including ovaries and uterus in females and prostate gland and testes with epididymis and seminal vesicles in males.

One female mouse in the 1000 mg/kg group died of a dosing accident during week 11. Mean body weights of 2000 mg/kg females were significantly less than those of the vehicle control group. Ruffled fur was observed in two 1000 mg/kg males between weeks 7 and 8 and all 2000 mg/kg males between weeks 5 and 9. No treatment-related differences were observed in sperm parameters in males administered 500, 1000, or 2000 mg/kg or in the estrous cycle of females administered 500 or 1000 mg/kg when compared to controls. Female mice in the 2000 mg/kg group had a significantly higher probability of extended estrous than did the vehicle control females. Liver weights of males of the 250 mg/kg or greater dose groups and females of all dose groups were significantly greater than those of the vehicle control groups. Kidney weights of males of the 2000 mg/kg group were significantly less than those of the vehicle control group. Incidences of hepatic cell hypertrophy were significantly increased in males and females dosed with 250 mg/kg or greater. Significantly increased incidences of focal hepatocytic necrosis occurred in males of the 1000 and 2000 mg/kg dose groups. The incidences of hyaline droplet accumulation in the respiratory epithelium of the nose were significantly increased in males of the 500 mg/kg and females of the 1000 and 2000 mg/kg dose groups. In the olfactory epithelium of the nose, the incidences of hyaline droplet accumulation were significantly increased in the 125 (female only), 500, and 1000 mg/kg groups. Incidences of atrophy of the olfactory epithelium were significantly increased in the 1000 mg/kg groups. The incidences of pigment accumulation in macrophages in the olfactory epithelium were significantly increased in males in the 500 mg/kg or greater groups and in females in the 1000 and 2000 mg/kg dose groups.

The NTP also performed a 3-month study of the same GBE used above in rats. Groups of 10 male and 10 female F344/N rats received 0, 62.5, 125, 250, 500, or 1000 mg/kg body weight of the GBE in corn oil via gavage, 5 days per week for 14 weeks. Additional groups of 10 male and 10 female rats received the same doses for a clinical pathology study, 5 days per week for 23 days. Control groups received corn oil (2.5 ml/kg). The same methods that were followed in the mouse study described above were used in the main study animals, while animals in the clinical pathology study had blood samples collected on days 4 and 23.

All rats survived to the end of the study. Mean body weights of all dosed groups were similar to those of the vehicle control groups. No treatment-related clinical findings were observed. Liver weights of all dosed groups of males and females
were significantly greater than those of the vehicle control groups. Incidences of hepatocyte hypertrophy in all dosed groups of males and in 500 and 1000 mg/kg females were significantly greater than those in the vehicle control groups; there was a dose-related increase in severity of this lesion in males. “Hepatocyte fatty change” occurred in all dosed males. The incidences of thyroid gland follicular cell hypertrophy were significantly increased in 500 and 1000 mg/kg males and in 1000 mg/kg females. The incidences of pigmentation in the olfactory epithelium of the nose were significantly increased in 500 and 1000 mg/kg males and in females administered 125 mg/kg or greater.8

**Ginkgo Biloba Meristem Cell**

**Oral**

In a 13-week oral study, groups of 10 male and female Sprague-Dawley rats received 250, 500, or 1000 mg/kg Ginkgo Biloba Meristem Cell (further dosing details were not provided).46 Observations made during the treatment period included clinical signs of toxicity, body weight and feed measurements, ophthalmology assessment, and urinalysis. At study end, necropsy, hematological/biochemical examinations of blood, organ weight measurement, microscopic examination, and histopathological examination were performed. No unscheduled deaths or adverse clinical signs of toxicity were observed during the treatment period in any dose group. No treatment-related adverse changes were reported in any of the measured parameters before or after necropsy. Based on the results of this study, the no-observed-adverse-effect-level (NOAEL) in rats for Ginkgo Biloba Meristem Cell was determined to exceed 1000 mg/kg.

**Chronic Toxicity Studies**

**Oral**

There was no evidence of organ damage or impairment of hepatic or renal function when a standardized GBE (EGb 761®) was administered orally over 27 weeks to rats and mice at doses ranging from 100 to 1600 mg/kg.45 No further details were provided.

The results of the NTP chronic toxicity bioassays are summarized in the Carcinogenicity section below.

**DEVELOPMENTAL AND REPRODUCTIVE TOXICITY (DART) STUDIES**

**Oral**

The reproductive and developmental toxicity of a standardized GBE (EGb 761®) was studied in mice. In one study, groups of 25 mated female CD-1 mice received 0, 100, 350, or 1225 mg/kg/day GBE in tap water via gavage (20 ml/kg) on days 6 through 15 of gestation.48 The dams were observed daily for clinical signs of toxicity. Feed and water consumption were monitored during the study. Body weight was measured daily. On day 17 of gestation, the dams were killed and the ovaries, uteri, and the fetuses were removed. The internal organs and the placenta of the dams were examined macroscopically. The fetuses were examined for several parameters, including external and internal damages (malformations), sex, viability, and weight. The skeletal systems and soft tissues of the fetuses were also examined. No clinical signs of toxicity were observed in the dams and there were no unscheduled deaths. No treatment related effects were observed in body weight gains or feed and water consumption. There were no pathological findings observed during necropsy. No embryotoxic effects were observed during external and internal examinations of the fetuses nor were any observed in skeletal or soft tissues. There were no increased incidences of malformation, variations, or retardations. The authors concluded the no-observed-effect-level (NOEL) was greater than 1225 mg/kg/day for both the dams and the fetuses in this study of a standardized GBE.48

Another study examined the effects of oral administration of a standardized GBE (EGb 761®) in saline on the mouse reproductive and developmental toxicity.49 Female Swiss albino mice received 0, 3.7, 7.4, or 14.8 mg/kg body weight/day for 28 days prior to mating, from day 1 to day 7 of gestation, or from day 10 to day 18 of gestation. There were 10 animals per dose group to study the anti-implantation and abortifacient activities for this GBE, while there were 10 mice per dose group to study the reproductive cycle and 20 mice per dose group to study the developmental cycle (12 test groups total). Blood hormones were measured in the pre-mating group on day 28. Vaginal smears were performed daily. The mice were observed daily for clinical signs of toxicity and premature deaths. Body weights were recorded weekly. On day 20 of gestation, the remaining mice were killed and their kidneys, liver, brain, placenta, spleen and ovaries were removed and weighed. The ovaries were prepared for histological examinations, and then ovarian follicles were counted. Maternal toxicity, estrous cycle, reproductive hormones, ovarian follicle counts, resorption index, implantation index, fetal viability and fetuses, and placenta mean weights were evaluated.

No symptoms of clinical toxicity such as depressed activities, respiratory distress, salivation, tremor, fasciculation, dull eyes, diarrhea, or change in fur appearance were observed in the dams during treatment, and there were no unscheduled deaths. Statistically significant decreases in body weight gains were observed in the 14.8 mg/kg/day dose group when compared to the controls. There were no treatment-related differences in the relative weights of the liver, kidney, brain, spleen, ovary, and placenta, but there was a significant dose-dependent decrease in the relative weight of the gravid uterus in the 14.8 mg/kg/day dose group for 28 days when compared to controls. Ovarian follicle counts, resorption index, implantation index, and fetal viability were significantly reduced in 14.8 mg/kg/day dose group. Treatment with 14.8 mg/kg bw/day of
this particular GBE induced disruption of estrous cycle and caused maternal toxicity, in addition to fetal toxicity. No adverse effects were observed in the 3.7 or 7.4 mg/kg bodyweight/day dose groups. The authors concluded that 14.8 mg/kg body weight/day of this GBE produced adverse effects on the estrous cycle, fertility, abortifacient, reproductive performance, and hormone levels of female mice and may cause adverse effects on ovarian function as an antifertility agent.49

The effects of an aqueous GBE (similar to EGb 761) on embryo-fetal development were investigated in pregnant Wistar rats.50 Groups of 17 rats received 0, 3.5, 7, or 14 mg/kg/day of the test material during the tubal transit and implantation period of pregnancy. The dams were then killed on the 15th day of pregnancy. The following parameters were evaluated during the study: clinical symptoms of maternal toxicity; maternal body weight; feed and water intake; maternal liver, kidney, and ovary weights; number of corpora lutea; implants per group ratio; pre- and post-implantation loss per group ratio; live fetuses mean; dead fetuses percentage; fetus and placenta weight per offspring ratio; and fetal external malformation. No significant adverse effects were observed for any of the parameters in the dams or the embryos. The authors of this study concluded that the studied GBE did not produce adverse effects in maternal or embryonic rats.

**GENOTOXICITY**

**In Vitro**

**Ginkgo Biloba Leaf Extract**

The NTP tested a specific GBE at up to 10,000 µg/plate was mutagenic in an Ames test using *Salmonella typhimurium* strains TA98 and TA100 and *Escherichia coli* strain WP2 uvrA/pKM101, with and without metabolic activation.6

The genotoxicity of the same GBE and eight of its constituents (quercetin; quercetin-3-β-D-glucoside; kaempferol; isorhamnetin; ginkgolide A; ginkgolide B; ginkgolide C; and bilobalide) were evaluated in mouse L5178Y cells using a lymphoma assay and a Comet assay.51 The GBE (0.2-1.2 µg/ml) and the eight constituents were tested in a dimethyl sulfoxide (DMSO) solution. A dose-dependent increase in mutant frequency was observed in the studied GBE, quercetin (10-100 µM), quercetin-3-β-D-glucoside (200-1000 µM), and kaempferol (10-200 µM) without metabolic activation. DNA double-strand breaks were also observed in dose-dependent increases in the studied GBE, quercetin, and kaempferol. Negative results were observed in the other constituents. A Western blot analysis confirmed that GBE, quercetin, and kaempferol activated the DNA damage signaling pathway. Additionally, GBE produced reactive oxygen species and increased glutathione levels in L5178Y cells. An analysis of loss of heterozygosity in *Ty••* mutants indicated that GBE, quercetin, and kaempferol resulted in extensive chromosomal damage. The authors concluded that the studied GBE, quercetin, and kaempferol are mutagenic in mouse L5178Y cells.

**Ginkgo Biloba Meristem Cell**

Ginkgo Biloba Meristem Cell at up to 5000 µg/plate was not mutagenic in an Ames test in *S. typhimurium* strains TA98, TA100, TA1535, and TA1537 or in *E. coli* strain WP2 uvrA/pKM101, with and without metabolic activation.46 Ginkgo Biloba Meristem Cell did not induce chromosomal aberrations in Chinese hamster lung cultured cells, with and without metabolic activation. The cells were treated with 210.0 µg/ml without metabolic activation (short-time treatment), 333.6 µg/ml with metabolic activation (short-time treatment), and 202.2 µg/ml without metabolic activation (24 h continuous treatment). Short-time treatment was not defined.

**In Vivo**

**Ginkgo Biloba Leaf Extract**

In a micronucleus test in male and female B6C3F1/N mice performed by the NTP, no increase in the frequency of micronucleated erythrocytes was observed in peripheral blood of male mice administered 125 to 2000 mg/kg/day of a GBE orally for 3 months.8 Female mice that received the same doses had results that were deemed equivocal based on a significant trend test and due to no individual dose group being significantly elevated over the vehicle control group. A significant (P < 0.001) dose-related decreased in the percentage of circulating polychromatic erythrocytes (PCEs) was observed in male mice, which may indicate the studied GBE induced bone marrow toxicity. In the female mice, a significant (P = 0.001) decrease in the percentage of circulating PCEs was also observed, but the response was not as correlated with dose as it was in the males.

In a reporter gene mutation assay using male B6C3F1 gpt delta mice, oral dosing of the GBE used in the NTP studies at up to 2000 mg/kg body weight/day (in corn oil) for 90 days did not produce remarkable increases in gpt or Spi mutations in DNA extracted from the liver.27 No treatment-related clinical signs or deaths were observed during the treatment period. Relative liver weights were significantly increased in the 2000 mg/kg group. Hepatocellular hypertrophy in the centrilobular area and slight focal necrosis were observed in the 2000 mg/kg group.

This assay was performed in conjunction with a combined liver comet assay and bone marrow micronucleus assay using male and female CARKO and wild-type mice. The short-term toxicity effects were described in the Toxicological Studies section. In the micronucleus study, no significant alterations in the percentages of PCEs were observed in females of either genotype; however, a significant decrease in the percentage of PCEs was observed in both genotypes in males,
indicating the studied GBE induced bone marrow toxicity in male mice. In the comet assay, there was no significant difference in the percent tail DNA in any of the GBE-treated groups in either mouse genotype. Heavily damaged cells called “hedgehogs” indicating cytotoxic effects were not detected in any animals. The researchers performing these 3 assays concluded that the studied GBE is not genotoxic.47

**Ginkgo Biloba Meristem Cell**

In a micronucleus test, no increase in the frequency of micronucleated polychromatophilic erythrocytes in bone marrow was observed in male mice administered 500 to 2000 mg/kg/day Ginkgo Biloba Meristem Cell.46 There was no significant difference in the ratio of polychromatophilic erythrocytes in total red blood cells when compared to the negative control. The positive control yielded expected results. No further details were provided.

**CARCINOGENICITY**

**Oral**

The carcinogenic potential of a GBE administered orally was studied by the NTP in male and female rats and mice.8 In the study on mice, groups of 50 male and 50 female B6C3F1/N mice received 200, 600, or 2000 mg/kg of this GBE in corn oil 5 day per week for 104 weeks via gavage. In the study on rats, groups of 50 F344/N male and 50 female rats received 100, 300, or 1000 mg/kg body weight of this GBE for 104 (males) or 105 (females) weeks via gavage. Control groups received corn oil (5 ml/kg in mice and 2.5 ml/kg in rats). In rats involved in what was deemed a “special study,” groups of 10 male and female rats received the same doses as in the main study; blood was collected from these rats on day 22 and at week 14 for thyroid hormone analyses and other analyses of the liver and thyroid gland. All animals were observed twice daily. Body weights were evaluated at study beginning and ending and at different intervals during the course of the study. At the end of the study period, tissues from over 40 sites were examined for every animal, including ovaries and uteri in females and prostate gland and testes with epididymis and seminal vesicles in males.

In mice, mortality was significantly higher in the 600 and 2000 mg/kg males than in the vehicle controls, with the most frequent cause of death being liver tumors. Survival in the 600 mg/kg females was significantly greater than that of the vehicle controls. Mean body weights in the mid- and high-dose group male mice were less than (10% or more) those of the vehicle controls after weeks 85 and 77, respectively. The mean body weights of the high-dose females were generally less than the vehicle controls between weeks 17 and 69 and after week 93.

In rats, mortality in the 1000 mg/kg males was significantly higher than that of the vehicle controls, with the most frequent cause of death being mononuclear cell leukemia. The survival of the treated groups of female rats was comparable to the vehicle control. In week 14, all dose group males and females of the 1000 mg/kg group in the special study had increased levels of thyroid stimulating hormone compared to the vehicle controls; the increase was dose-related in the male rats. Mean body weights in the mid- and high-dose male and female rats were less than (10% or more) those of the vehicle controls after weeks 93 and 89, respectively.

Lesions in the liver, thyroid gland, and nose were observed in all the studied GBE dose groups in mice and rats. These lesions included hypertrophy in the liver and thyroid gland in rats and mice, liver hyperplasia in male and female rats, and hyperplasia and atrophy of the epithelium in the nose of male and female rats. Inflammation, hyperplasia, hyperkeratosis, and ulcers were also observed in the forestomach of male and female mice. Additionally, increased incidences of cancers of the thyroid gland were observed in male and female rats and male mice and of liver cancers in male and female mice. The study concluded that the studied GBE caused cancers of the thyroid gland in male and female rats and male mice, and cancers of the liver in male and female mice.8

In dietary carcinogenicity studies of a standardized GBE (EGb 761®) in mice (at up to 200 mg/kg/day) or rats (at up to 100 mg/kg/day), no neoplastic or pre-neoplastic effects were observed.52 The rodents received the test material for up to 85 weeks. No changes in body weight gain were reported. No further details are available.

The International Agency for Research on Cancer (IARC) has determined that GBEs are possibly carcinogenic to humans (group 2B) based on inadequate human carcinogenicity evidence and sufficient evidence in experimental animals.53 The animal data used to reach this determination were from the NTP studies that are described above that used a specific GBE. IARC reviewed the findings of a few randomized and case-control epidemiological studies research the potential effects of the use of GBE dietary supplements in elderly patients and ovarian cancer patients. IARC suggested that the mechanisms for carcinogenicity associated with GBEs may be genotoxicity and/or topoisomerase inhibition that could be related to the constituents quercetin, kaempferol, and/or rutin.

**OTHER RELEVANT STUDIES**

**Immunotoxicity**

In a popliteal lymph node assay (PLNA), the sensitization potential of a GBE was evaluated.12 Groups of male C57BL/6 mice received subplantar injections of 10 µl DMSO (induction) followed by another injection of DMSO (negative control group), a crude ethanolic-aqueous GBE, heptane fraction of the crude GBE, or diphenylhydantoin (positive control group) at doses of 2 mg each. The negative control yielded small enlargement of the lymph nodes, while the crude ethanolic-
aqueous GBE resulted in statistically significant lymphoproliferative reaction (LPR) in the ipsilateral popliteal lymph node. A massive lymph node hyperplasia that was almost comparable to the positive control was observed in the heptane solution fraction of the crude GBE. Chemical analyses of the crude extract and the heptane fraction found ginkgolic acid at 5.5% and 24.6%, respectively, which were theorized to be responsible for the LPR observed in this study.

**DERMAL IRRITATION AND SENSITIZATION STUDIES**

**Irritation**

**Human**

No irritation was observed in a 24-h human patch test of a Ginkgo Biloba Leaf Extract (100%; ethanol:water:butylene glycol extract) in 20 subjects. No further details were provided.

**Sensitization**

**Animal**

The sensitizing potential of ginkgolic acid and a GBE was studied in 10 female albino guinea pigs using a modified Freund’s complete adjuvant (FCA) technique. The pure ginkgolic acid was extracted from *Ginkgo biloba* fruit and the GBE was a prepared through water:acetone extraction and contained 24% flavone glycosides and ~1000 ppm (~0.1%) ginkgolic acid. The animals received intradermal injections (up to 0.15 ml) of an emulsion containing 4 ml physiological saline, 4 ml FCA, 15 mg of the pure ginkgolic acid, and 30 mg ginkgolic acid-containing leaf extract on to the clipped and shaved shoulder area on days 1, 5, and 9 of the study. After an 11 day rest period, the animals were challenged with 0.1% and 1% ginkgolic acid and 10% GBE in acetone on the clipped and shaved right flank. All animals exhibited sensitization to pure ginkgolic acid, while none were sensitized to the GBE that contained 1000 ppm ginkgolic acid.

**Human**

Human dermal sensitization studies are summarized in Table 6. No dermal irritation or sensitization was observed in human repeat insult patch tests (HIRIPs) of products containing up to 0.2% Ginkgo Biloba Leaf Extract.

**Cross-Reactivity**

Guinea pig sensitization studies of crude *Ginkgo biloba* fruit extract, the main aromatic components of the fruit, and urushiol found no cross-reactions among the compounds. It was also determined that ginkgolic acid was the main allergen in *Ginkgo biloba*.

**Phototoxicity/Photosensitization**

No phototoxicity or photosensitization was reported to a lip product containing 0.0072% Ginkgo Biloba Leaf Extract in a study of 29 subjects. The test material was applied neat under semi-occlusive patches. No further details were provided.

**OCULAR IRRITATION STUDIES**

In an EpiOcular in vitro assay of an eye product containing 0.013% Gingko Biloba Leaf Extract, it was predicted that the test substance had no potential for eye irritation. No further details were provided.

**CLINICAL STUDIES**

**Case Studies**

The fruit pulp of the *Ginkgo biloba* tree has been reported to cause contact dermatitis, with several cases reported after patients handled the fruit pulp during extraction of the edible nut center. Symptoms include intense itching, edema, papules, and pustules that usually resolve in 7-10 days.

A 66-year-old woman presented with progressive erythematos eruption over the face, neck, trunk, and extremities that started approximately one week after the patient had ingested two 60 mg doses of a GBE supplement. No other new medications or changes in behavior were reported. A physical examination, complete blood cell count, and chemistry panel were unremarkable. The authors of the report did not disclose if patch or skin prick tests were performed.

A 45-year-old man developed acute generalized exanthematous pustulosis on his limbs and face 48 h after starting an oral GBE treatment for tinnitus. The patient had not previously taken any GBEs before and was not taking any other medication. The patient had no history of adverse drug reactions or psoriasis. The rash cleared within 10 days of stopping the GBE treatment. The patient refused a follow-up cutaneous patch test.

In anecdotal accounts from Chinese medicine, consumption of fresh *Ginkgo biloba* nuts may cause stomachache, nausea, diarrhea, convulsions, weak pulse, restlessness, difficulty breathing, and shock. Death has been reported in children following consumption of fresh nuts.
Other Clinical Reports

No adverse effects were reported in clinical studies of a cosmetic formulation containing 1.5% GBE and other antioxidants in 45 volunteers (twice daily for 90 days)\textsuperscript{62} and of a cosmetic formulation containing 0.30% GBE in 20 volunteers (twice daily for 28 days).\textsuperscript{63}

Numerous studies have investigated the efficacy and safety of GBEs in humans in the treatment of various afflictions. In a cross-matching review of much of this published toxicological and clinical data on GBEs (mainly the herbal supplement EGb 761\textsuperscript{8}), the authors of the review evaluated the findings of 75 clinical studies with a total of 7115 patients treated orally with GBEs and found no specific or serious undesired reactions to GBEs.\textsuperscript{52} Any adverse events observed frequently occurred at the same frequency as placebo treatments. Based on cross-matching data on the historic use by humans, large intake, toxicological and clinical studies, the authors concluded that GBEs are well tolerated and safe.

**SUMMARY**

According to the Dictionary, most of the *Ginkgo biloba*-derived ingredients detailed in this safety assessment are reported to function as skin conditioning agents, while some are reported to function as antioxidants in cosmetics. Investigations into the efficacy of the leaf extract for these uses are numerous and are mainly based on oral administration of supplements. There are no publically available toxicity data that corresponds to specific use of these ingredients as cosmetics. This safety assessment focuses on data relevant to the use of *Ginkgo biloba*-derived ingredients in cosmetics, with specific attention on dermal application when available.

According to 2017 VCRP survey data, *Ginkgo Biloba* Leaf Extract has the most reported uses in cosmetic products, with a total of 726; the majority of the uses are in leave-on eye makeup preparations and skin care products. Two other *Ginkgo*-derived ingredients are reported to be in use, with 24 or less uses reported in the VCRP. The results of the concentration of use survey on these 10 ingredients conducted in 2014 by the Council indicate use for only *Ginkgo Biloba* Leaf Extract, which is reported to be used at a maximum of 1%, as reported in face and neck skin preparations.

GBEs are used extensively as an herbal supplement for anti-inflammatory, cognitive-promoting, antioxidant, and vascular effects and is an approved herbal medicine in Germany for use for treatment of memory deficits, dementia, and other organic brain syndromes when extracted with acetone/water. GBEs may interact with pharmaceutical drugs. Nuts from *Ginkgo biloba* are consumed as a delicacy in Japan and China and are used in traditional Chinese medicine. Anecdotal accounts report that consumption of the nuts may have acute adverse effects.

In general, toxicokinetics data are not expected to be found on botanical ingredient because each botanical ingredient is a complex mixture of hundreds of constituents. However, there have been many pharmacokinetics studies on GBEs, specifically on some of the key constituents, which indicate GBEs may be well absorbed after oral administration. The GBE constituent, quercetin, was found to penetrate human dermatomed skin. In an oral ADME study in rats, at least 60% of a radiolabeled GBE (flavonol glycosides and proanthocyanidins) were absorbed, with the main site of absorption likely in the upper gastrointestinal tract. Radioactivity was measured in exhalation and elimination products. In a human plasma study ginkgolide A, ginkgolide B, and bilobalide were found to be bioavailable after single oral dosing of 3 different *Ginkgo biloba* preparations.

The LD\textsubscript{50} of a standardized GBE (EGb 761\textsuperscript{8}) administered orally to mice was reported to be 7730 mg/kg, and the LD\textsubscript{50} after intravenous administration with this standardized GBE was 1100 mg/kg for both rats and mice. The lethal dose for *Ginkgo Biloba* Meristem Cell was greater than 2000 mg/kg in rats and the maximum tolerated dose for this ingredient was greater than 1000 mg/kg in dogs.

In 3-month studies by the NTP of a specific GBE at up to 2000 mg/kg/day, increased liver weights, decreased kidney weights, increased incidences of hepatocytic hypertrophy and focal hepatocytic necrosis, and increased incidences hyaline droplet accumulation, atrophy and pigment accumulation in macrophages in the olfactory epithelium were observed in mice. In a similar NTP study of the same GBE test material in rats, increased liver weights, increased incidences of hepatocyte hypertrophy, increased incidences of thyroid gland follicular cell hypertrophy, and increased incidences of pigmentation in the olfactory epithelium of the nose were observed. There was no evidence of organ damage or impairment of hepatic or renal function when a GBE (EGb 761\textsuperscript{8}) was administered orally over 27 weeks to rats and mice at doses ranging from 100 to 1600 mg/kg. In a 4-week oral repeated dose study, no adverse effects were observed in rats that received up to 2000 mg/kg *Ginkgo Biloba* Meristem Cell. In the follow-up 13-week oral study, the NOAEL in rats for *Ginkgo Biloba* Meristem Cell was greater than 1225 mg/kg.

In an oral DART study of a standardized GBE (EGb 761\textsuperscript{8}) in mice, the NOEL for dams and fetuses was greater than 1225 mg/kg/day. No clinical signs of toxicity were observed in the dams and no embryotoxic effects were observed in the fetuses. In another oral DART study in mice, a standardized GBE (EGb 761\textsuperscript{8}) at 14.8 mg/kg/day produced adverse effects on the estrous cycle, fertility, abortifacient, reproductive performance, and hormone level in female mice and may cause adverse effects on ovarian function as an antifertility agent. No adverse effects in maternal or embryonic rats were observed in an embryo-fetal development study in rats at doses up to 14 mg/kg/day of an aqueous GBE similar to EGb 761\textsuperscript{8}.

The GBE specific to NTP studies was mutagenic in an Ames test at up to 10,000 µg/plate, and the same GBE (0.2 - 1.2 mg/ml) was mutagenic in mouse L5178Y cells. The authors of a cross-matching review of the GBE herbal supplement EGb761\textsuperscript{8} concluded that the positive findings in some in vitro genotoxicity tests are linked to cytotoxic effects of *Ginkgo*...
biloba extract and the use of very high test concentrations compared to therapeutic use concentrations. In a mouse micronucleus test of the same GBE at up to 2000 mg/kg/day, no increase in the frequency of micronucleated erythrocytes was observed in male mice, but the results were deemed equivocal in female mice. The same GBE at up to 2000 mg/kg/day was not genotoxic in a reporter gene mutation assay, a combined liver comet assay, and bone marrow micronucleus assay in mice. Ginkgo Biloba Meristem Cell was not mutagenic in an Ames test at up to 5000 μg/plate, nor did it induce chromosomal aberrations in Chinese hamster lung cultured cells, with and without metabolic activation. Ginkgo Biloba Meristem Cell did not increase the frequency of micronucleated erythrocytes in male mice at up to 2000 mg/kg/day.

In oral carcinogenicity studies of rats and mice conducted by the NTP, lesions in the liver, thyroid gland and nose were observed in all GBE dose groups (200 - 2000 mg/kg/day, by gavage). Lesions included hypertrophy in the liver and thyroid gland in rats and mice, liver hyperplasia in male and female rats, and hyperplasia and atrophy of the epithelium in the nose of male and female rats. Inflammation, hyperplasia, hyperkeratosis, and ulcer were also observed in the forestomach of male and female mice. Additionally, increased incidences of cancers of the thyroid gland were observed in male and female rats and male mice, as were liver cancers in male and female mice. In dietary carcinogenicity studies of a standardized GBE (Egb 761®) in mice (at up to 200 mg/kg/day) or rats (at up to 100 mg/kg/day) for up to 85 weeks, no neoplastic or pre-neoplastic effects were observed. IARC has determined that GBEs are possibly carcinogenic to humans (group 2B).

In a PLNA validation study, a GBE exposure yielded statistically significant lymphoproliferative reactions in the ipsilateral popliteal lymph node, which was may have been caused by ginkgolic acid. No irritation was observed in a 24-h human patch test of Ginkgo Biloba Leaf Extract (100%; ethanol:water:butylene glycol extract).

In a guinea pig study, sensitization was observed to ginkgolic acid at concentrations of 0.1% and 1%, but no sensitization was observed to a GBE that contained ~1000 ppm (~0.1%) ginkgolic acid. No dermal sensitization was reported in HRIPTs of products containing 0.2% Ginkgo Biloba Leaf Extract.

Guinea pig sensitization studies of crude Ginkgo biloba fruit extract, the main aromatic components of the fruit, and urushiol found no cross-reactions among the compounds. It was also determined that ginkgolic acid was the main allergen in Ginkgo biloba.

No phototoxicity or photosensitization was reported to a lip product containing 0.0072% Ginkgo Biloba Leaf Extract.

No ocular irritation was predicted in an in vitro assay using an eye product containing 0.013% Ginkgo Biloba Leaf Extract.

Reports of contact dermatitis have been reported following exposure to the fruit pulp of Ginkgo biloba. Patients have reported erythematous reactions and generalized exanthematous pustulosis following ingestion of certain GBE supplements. No adverse effects were reported in clinical studies of cosmetic formulations containing up to 1.5% GBEs. In anecdotal accounts from Chinese medicine, consumption of fresh Ginkgo biloba nuts may cause stomachache, nausea, diarrhea, convulsions, weak pulse, restlessness, difficulty breathing, and shock. Death has been reported in children following consumption of fresh nuts. A cross-matching review of multiple clinical studies found no specific or serious undesired reactions to GBEs (mainly EGb 761®).

**DISCUSSION**

The ingredients in this report are each a mixture of botanical constituents derived from the plant Ginkgo biloba. Because final product formulations may contain multiple botanicals, each possibly containing similar constituents of concern, formulators are advised to be aware of these constituents and to avoid reaching levels that may be hazardous to consumers. For Ginkgo biloba-derived ingredients, the Panel was concerned about the presence of ginkgolic acid, which is a known dermal sensitizer. The Panel determined that the current data regarding the concentration levels of ginkgolic acid and data on dermal sensitization in Ginkgo biloba-derived cosmetic ingredients at use concentrations are insufficient.

The Panel considered the findings of the National Toxicology Program’s (NTP’s) carcinogenicity studies of a Ginkgo biloba leaf extract where positive carcinogenic effects were observed in animals, especially in the high dose groups. The Ginkgo biloba leaf extract evaluated by the NTP contained unusually high concentrations of certain constituents that are markedly different from those found in the leaf extracts used in dietary supplements. The NTP study administered this specific leaf extract at high doses by gavage, allowing for concentrations in the blood that would not be achieved through cosmetic use. The leaf extract similar to that used in dietary supplements did not produce increased incidences of cancer in a dietary study. This, combined with a long history of use of Ginkgo biloba leaf extracts in folk medicine, indicate that the findings of the NTP’s carcinogenicity study are not relevant to cosmetic use in humans.

The Panel also expressed concern about pesticide residues, heavy metals, and other plant species that may be present in botanical ingredients. They stressed that the cosmetics industry should continue to use current good manufacturing practices (cGMPs) to limit impurities.

Ginkgo Biloba Leaf Extract was reported to be used in spray and powder products that could possibly be inhaled, such as pump spray suntan products at a maximum concentration of 0.05%, and face powders at a maximum concentration of 0.05%. There were no inhalation toxicity data available. Although the Panel noted that droplets/particles from spray and loose-powder cosmetic products would not be respirable to any appreciable amount, the potential for inhalation toxicity is not
limited to respirable droplets/particles deposited in the lungs. In principle, inhaled droplets/particles deposited in the nasopharyngeal and thoracic regions of the respiratory tract may cause toxic effects depending on their chemical and other properties. However, coupled with the small actual exposure in the breathing zone and the concentrations at which the ingredients are used, the available information indicates that incidental inhalation would not be a significant route of exposure that might lead to local respiratory or systemic effects. A detailed discussion and summary of the Panel’s approach to evaluating incidental inhalation exposures to ingredients in cosmetic products is available at http://www.cir-safety.org/cir-findings.

After reviewing this safety assessment, the Panel found that the data are insufficient to determine the safety of the Ginkgo biloba-derived ingredients detailed in this report. The data needed to issue a conclusion of safety for these cosmetic ingredients are:

- Method of manufacturing, composition, and impurities data for each of these ingredients, except Ginkgo Biloba Meristem Cell;
- 28-Day dermal toxicity data for each of these ingredients,
  - Dependent on the results of these studies, additional data on other toxicological endpoints, such as developmental and reproductive toxicity and carcinogenicity, may be needed;
- Dermal irritation and sensitization data at leave-on use concentrations; and
- Ocular irritation data, if available.

**CONCLUSION**

The CIR Expert Panel concluded that the data are insufficient to determine the safety of the following 10 Ginkgo biloba-derived ingredients.

NR = Not reported.

⁺ Because each ingredient may be used in cosmetics with multiple exposure types, the sum of all exposure types may not equal the sum of total uses.

* Combined with the generic entry “Ginkgo Extract” in the VCRP database, which is not an INCI name.

* It is possible these products may be sprays, but it is not specified whether the reported uses are sprays.

ᵇ Not specified whether a powder or a spray, so this information is captured for both categories of incidental inhalation.

ᶜ It is possible these products may be powders, but it is not specified whether the reported uses are powders.
