
Safety Assessment of Xanthine Alkaloids as Used in Cosmetics

Status: Scientific Literature Review for Public Comment
Release Date: August 2, 2018
Panel Meeting Date: September 24-25, 2018

All interested persons are provided 60 days from the above release date to comment on this safety assessment and to identify additional published data that should be included or provide unpublished data which can be made public and included. Information may be submitted without identifying the source or the trade name of the cosmetic product containing the ingredient. All unpublished data submitted to CIR will be discussed in open meetings, will be available at the CIR office for review by any interested party and may be cited in a peer-reviewed scientific journal. Please submit data, comments, or requests to the CIR Executive Director, Dr. Bart Heldreth.

The 2018 Cosmetic Ingredient Review Expert Panel members are: Chairman, Wilma F. Bergfeld, M.D., F.A.C.P.; Donald V. Belsito, M.D.; Ronald A. Hill, Ph.D.; Curtis D. Klaassen, Ph.D.; Daniel C. Liebler, Ph.D.; James G. Marks, Jr., M.D., Ronald C. Shank, Ph.D.; Thomas J. Slaga, Ph.D.; and Paul W. Snyder, D.V.M., Ph.D. The CIR Executive Director is Bart Heldreth, Ph.D. This safety assessment was prepared by Priya A. Cherian, Scientific Analyst/Writer.

INTRODUCTION

This scientific literature review is the initial step in preparing a safety assessment of the following 3 xanthine alkaloid ingredients in cosmetic formulations:

Caffeine
Theophylline
Theobromine

According to the web-based *International Cosmetic Ingredient Dictionary and Handbook* (wINCI;Dictionary), Caffeine, Theophylline, and Theobromine are structurally similar to one another and are reported to function as skin-conditioning agents in cosmetic products.¹ Caffeine and Theobromine are also reported to function as fragrance ingredients in cosmetics (Table 1).

This safety assessment includes relevant published and unpublished data that are available for each endpoint that is evaluated. Published data are identified by conducting an exhaustive search of the world's literature. A listing of the search engines and websites that are used and the sources that are typically explored, as well as the endpoints that CIR typically evaluates, is provided on the CIR website (<http://www.cir-safety.org/supplementaldoc/preliminary-search-engines-and-websites>; <http://www.cir-safety.org/supplementaldoc/cir-report-format-outline>). Much of the information in this report was discovered in the European Chemicals Agency (ECHA) database²⁻⁴ or was available from the Organisation for Economic Cooperation and Development (OECD) Screening Information Dataset (SIDS) reports^{5,6}. Information from these sources is cited throughout the assessment. Please note that the ECHA website and OECD SIDS documents provides summaries of information generated by industry, and it is those summary data that are reported in this safety assessment.

CHEMISTRY

Definition and Structure

Alkaloids are naturally-derived, nitrogen-containing compounds.⁷ Xanthine alkaloids are intermediates in the degradation of adenosine monophosphate to uric acid. Caffeine, Theobromine, and Theophylline can be naturally or synthetically derived via the chemical synthesis of urea. The definitions and structures of the ingredients included in this report are presented in Table 1.¹ The ingredients in this group are methylated xanthine derivatives and are therefore structurally similar.

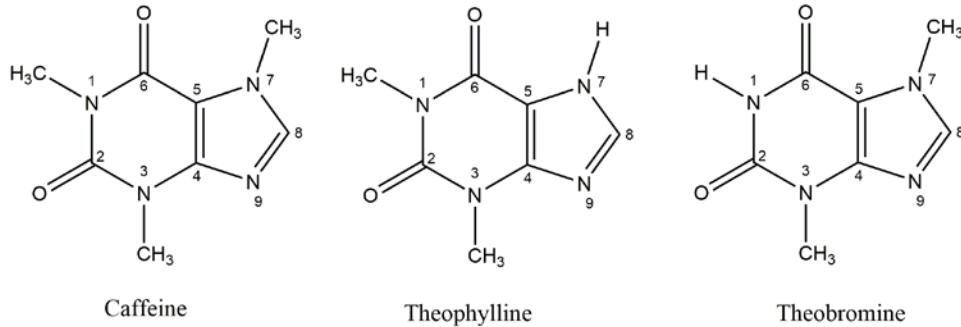

Figure 1. Xanthine alkaloids

Physical and Chemical Properties

The placement of the *N*-methyl groups determines the pharmacological profile of each ingredient.⁸ These methylated xanthines, notably Theobromine, are slightly to poorly soluble in water (Table 2).^{5,9-12,12} However, solubility is significantly increased in boiling water.

Method of Manufacture

Caffeine

The methods below are general to the processing of Caffeine for food or food ingredients, and it is unknown if they apply to cosmetic ingredient manufacture.

Caffeine can be extracted from plants or developed synthetically. Caffeine is most commonly extracted from green coffee beans, tea, or cola nuts.⁹ Dichloromethane, ethyl acetate, edible fats and oils, supercritical carbon dioxide and acid-activated carbon can each be used in the decaffeination process. For beans with moisture levels below 40%, direct bean decaffeination processes are applied, while for beans containing moisture levels of 60% or above, extract decaffeination techniques are

applied. Caffeine can be synthesized via methylation of Theobromine or Theophylline. For instance, Theophylline can be methylated with carbon monoxide and methanol.

When directly decaffeinating green coffee beans, beans are swollen with water and steam at a temperature of 20-100°C for a maximum of 5 hours.⁹ They are then decaffeinated in static or rotating drums with a solvent (dichloromethane, ethyl acetate or edible fats and oils). The beans are then steam stripped at 100-110 °C for a maximum of 4 hours, and dried to their initial moisture content via hot air or vacuum. The solvent is then evaporated or steam stripped under a vacuum to extract Caffeine, which is then purified via crystallization. Another bean decaffeinating technique includes the use of supercritical carbon dioxide at temperatures of approximately 40-80 °C and pressures of 200-300 bar for up to 30 hours. The Caffeine is dissolved and passed through a pressurized vessel.⁹

Extract decaffeination involves water as the extraction agent.⁹ The extract is decaffeinated by either liquid-liquid extraction with dichloromethane and steam deodorization or by selective adsorption of Caffeine on acid-activated carbon.

Theophylline

According to one method, the synthetic manufacturing of Theophylline comprises the reaction of dimethylurea and ethyl cyanoacetate.⁹ However, Theophylline is also naturally occurring and can be found in green coffee beans (*Coffea arabica* or *Coffea canephora*), black tea (*Camellia sinensis*), cocoa (*Theobroma cacao*) cotyledon, and dried mate (*Ilex paraguariensis*).

Theobromine

Theobromine can be produced synthetically from 3-methyluric acid, but is not typically derived this way.⁹ More commonly, Theobromine is obtained from natural sources, mainly found in the cocoa bean (*T. cacao*). The extraction of this ingredient typically occurs in the husks of the cocoa beans.

Impurities

Caffeine

United States Pharmacopeia (USP)-grade Caffeine must contain at least 98.5%.⁹ USP grade Caffeine must also not exceed a 0.5% or 8.5% weight loss upon drying the anhydrous form or hydrous form, respectively. In addition, the residue on ignition must not be more than 0.1%. In addition, USP-grade Caffeine must not contain more than 1 mg/kg lead.¹³

Theobromine

According to the *British Pharmacopeia*, Theobromine should be at least 99.0% of the product.⁹

Theophylline

Specifications for USP-grade Theophylline indicate that it be at least 97.0% of the active ingredient.⁹ USP-grade Theophylline also must not exceed a 0.5% weight loss upon drying for the anhydrous form, or 7.5-9.5% weight loss for the monohydrate form. In addition, the residue on ignition must not be more than 0.15%. The *British Pharmacopeia* states that Theophylline should not contain less than 99.0% active ingredient.⁹

Natural Occurrence

Caffeine

Caffeine can be found naturally worldwide in seeds, leaves, cocoa beans (*Theobroma cacao*) and other sources.⁹ The most common sources of Caffeine include coffee (*Coffea canephora* and *Coffea arabica*), cocoa beans, tea leaves, and guarana (*Paullinia cupana*). Coffee beans contain on average, 1.1% Caffeine in green coffee beans (*Coffea arabica*), and 2.2% in green robusta (*Coffea canephora*) beans. Tea plants can contain up to 5% Caffeine, but levels are dependent on seasonal variation, origin, and fertilizers.⁹

Theophylline

Theophylline is commonly found in black tea (*Camellia sinensis*), green coffee beans (*Coffea arabica*), dried mate (*Ilex paraguariensis*), and cacao (*Theobroma cacao*).⁹

Theobromine

Theobromine is also found in the same sources as identified above, but is primarily found in the cocoa plant (*Theobroma cacao*).⁹

USE

Cosmetic

The safety of the cosmetic ingredients addressed in this assessment is evaluated based on data received from the U.S. Food and Drug Administration (FDA) and the cosmetics industry on the expected use of these ingredients in cosmetics. Use frequencies of individual ingredients in cosmetics are collected from manufacturers and reported by cosmetic product category in the FDA Voluntary Cosmetic Registration Program (VCRP) database. Use concentration data are submitted by the cosmetic industry in response to a survey, conducted by the Personal Care Products Council (Council), of maximum reported use concentrations by product category.

According to 2018 VCRP survey data, Caffeine is reported to be used in 1033 formulations, 882 of which are leave-on products and 151 are rinse-off.¹⁴ Theobromine and Theophylline are reported to have much smaller frequencies of use at 5 formulations each. The results of the concentration of use survey conducted by the Council indicate Caffeine also has the highest concentration of use in a leave-on formulation; it is used at up to 6% in non-spray body and hand products.¹⁵ All ingredients reviewed in this report were reported to be in use, as described in Table 3.

Cosmetic products containing Caffeine and Theobromine are applied near the eyes (e.g., at maximum concentrations of 1.5% and 0.0025%, respectively, in eye lotions), and Caffeine is used in products that can result in incidental ingestion (e.g., at 0.2% in lipstick). Caffeine is also used in sprays (e.g., up to 0.2% in face and neck sprays) and powders (e.g., up to 2% in face powders), and these products can result in incidental inhalation. In practice, 95% to 99% of the droplets/particles released from cosmetic sprays have aerodynamic equivalent diameters >10 µm, with propellant sprays yielding a greater fraction of droplets/particles < 10 µm compared with pump sprays.^{16,17} Therefore, most droplets/particles incidentally inhaled from cosmetic sprays would be deposited in the nasopharyngeal and thoracic regions of the respiratory tract and would not be respirable (i.e., they would not enter the lungs) to any appreciable amount.^{18,19} Conservative estimates of inhalation exposures to respirable particles during the use of loose powder cosmetic products are 400-fold to 1000-fold less than protective regulatory and guidance limits for inert airborne respirable particles in the²⁰⁻²².

The xanthine alkaloids named in the report are not restricted from use in any way under the rules governing cosmetic products in the European Union.²³

Non-Cosmetic

Caffeine

Caffeine is most commonly used in beverages, such as coffee, tea and soft drinks. It can also be used as flavoring agents in baked goods, desserts, and candy.²⁴ The U.S. FDA has determined that Caffeine is generally recognized as safe (GRAS) when used in cola-type beverages at concentrations that are equal to or less than 0.02%. [21CFR182.1180] The average Caffeine intake of adults in the U.S. is 200 mg/day per individual.²⁴

A smaller percentage of Caffeine is used in over-the-counter (OTC) drug products, prescription drug products, and dietary supplements.²⁴ Caffeine is frequently used in analgesics as it may relieve headaches and pain associated with menstruation. Caffeine is also used in some medications to treat bronchopulmonary dysplasia and apnea in preterm infants. The U.S. FDA has determined that Caffeine is considered to be safe as an active ingredient in OTC weight control drug products and when used as an active ingredient in stimulant drug products at dosage limits of 100-200 mg every 3-4 hours for adults and children 12 and up. [21CFR182.1180]

Theobromine

Theobromine is mainly used in the production of Caffeine.⁹ The majority of consumed Theobromine is through chocolate/cocoa products. Theobromine is used as a bronchodilator, diuretic and vasodilator.

Theophylline

Theophylline is a bronchodilator and can be used to treat lung diseases such as bronchitis, asthma, and emphysema.⁹ It can also be used for the relief of biliary colic, and in diuretics.

TOXICOKINETIC STUDIES

Absorption, Distribution, Metabolism, and Excretion (ADME)

Caffeine

Caffeine is readily absorbed through body membranes. The typical half-life of Caffeine in humans, after oral consumption, is 2.5 - 4.5 hours, but the time is increased during the third trimester of pregnancy and in women taking oral contraceptives.⁵ Caffeine is widely distributed throughout body tissues, and is metabolized by hepatic enzyme systems, only. The majority of Caffeine, 70 - 80%, is metabolized through 3-N-demethylation to paraxanthine, carried out by the liver enzyme CYP1A2.²⁵

Approximately 7-8% of Caffeine is metabolized by 1-*N*-demethylation to Theobromine, while 1-*N*-demethylation to Theophylline also accounts for about 7-8% of Caffeine metabolism products.²⁵ The remaining Caffeine is metabolized through C-8 hydroxylation, resulting in the formation of 1,3,7-trimethyluric acid. However, outside of the liver, no significant metabolism of Caffeine occurs in other organs. The majority of Caffeine is excreted via urine (> 95% in humans).⁵

Theobromine

Theobromine can be seen in the body as a result of Caffeine metabolism. In humans, Theobromine is metabolized in the liver into xanthine, and further metabolized into methyluric acid, facilitated by CYP1A2 and CYP2E1.²⁶ Some mammals metabolize Theobromine at a slower pace, such as cats and dogs, which can result in Theobromine poisoning in amounts as small as 50 g. The approximate half-life of theobromine is 7.1 ± 0.7 hours. An estimated 10% of Theobromine is excreted via urine unchanged, while the rest is excreted as metabolites.

Theophylline

Theophylline is metabolized by ring oxidation and *N*-demethylation facilitated by microsomal enzymes in the liver (cytochrome P-450).⁶ Metabolites are excreted into bile and eliminated via urine. Only 7-12% of orally ingested Theophylline is excreted unchanged in urine. The major metabolites of Theophylline include 1,3-dimethyluric acid (35-55%), 1-methyluric acid (13-26%), and 3-methylxanthine (9-18%). After review of the kinetics and metabolism of Theophylline in rats, IARC concluded that Theophylline is quickly and completely absorbed from the digestive tract, readily crosses placental boundaries, can be distributed in breast milk, and is dispersed throughout all organs, with the exception of adipose tissue.⁹ Approximately 50% of Theophylline intake is bound to plasma proteins. The elimination half-time of Theophylline is approximately 3-11 hours in adults, which can be shortened or prolonged by certain medications and behaviors, such as smoking and oral contraceptives.

Animal

Oral

Theobromine

Theobromine was given to rabbits orally in doses of 1 and 5 mg/kg bw.⁹ Rabbits given these doses showed complete gastrointestinal absorption. Rabbits given high doses (10-100 mg/kg bw) displayed a reduction in absorption rate. Despite the reduced absorption rate, absolute bioavailability of the given Theobromine reached 100%.

A single dose of 15-50 mg/kg bw of Theobromine was given to dogs orally.⁹ Peak plasma concentrations were observed within 3 hours of dosing. Dogs given a high dose (150 mg/kg bw) had peak plasma concentrations 14-16 hours after dosing, implying delayed intestinal absorption.

Human

Dermal

Caffeine

A non-occlusive patch of 4 µg Caffeine/2.5 cm² in acetone was applied to the forearms of people from the age of 22 - 40 or 65 - 86.²⁷ After 24 hours, the site was washed and urine was collected. For the group with the age range of 22 - 40, the dose recovered was $32.1 \pm 4.2\%$. For the age group of 65 - 86, the dose recovered was $61.8 \pm 5.4\%$.

Oral

Caffeine

Four men were treated with 1, 4, and 10 mg/kg Caffeine via oral route.⁵ The absorption rate constant was 0.11 ± 0.02 hours⁻¹. Ninety-nine percent of the dose was absorbed. Metabolites were measured in plasma. Approximately 85% of the given dose was excreted in the urine. The main metabolites excreted were 1-methyluric acid, 1-methylxanthine, 1,7-dimethyluric acid, 7-methylxanthine, and 1,7-dimethylxanthine. In a similar study, plasma peak was reached at 47 ± 5 minutes. The mean plasma concentration was 8.3 ± 0.1 µg/mL, with an apportion rate constant of 6.3 ± 1.9 hour⁻¹ and elimination rate constant of 0.11 ± 0.02 hour⁻¹. Ninety-nine percent of the given dose was absorbed. The metabolites 3,7-dimethylxanthine, 1,3-dimethylxanthine, and 1,7-dimethylxanthine were measured in the plasma. Approximately 85% of the administered dose was recovered in the urine within 48 hours. The main metabolites excreted were 1-methyluric acid, 7-methylxanthine, and 1,7-dimethylxanthine.⁵

Nine pregnant and 4 post-partum women were exposed to Caffeine.⁵ Results showed a significant prolongation of Caffeine elimination in the pregnant women. Post-partum women showed normal rates of Caffeine elimination.

Thirteen males, 9 females not on oral contraceptive steroids (OCS), and 9 females taking OCS were examined.⁵ The elimination half time was significantly longer in women taking OCS. The average elimination half time for women taking

OCS was 10.7 hours, and 6.2 hours in women taking no OCS. Women on OCS had a total plasma clearance of 0.79 mm/min/kg, and free clearance of 1.12 ml/min/kg. Women not taking OCS had a total plasma clearance of 1.3 mm/min/kg and free clearance of 1.97 ml/min/kg. Kinetic parameters were similar in men and women, with the exception of volume of distribution, which was significantly higher in women.

A similar study was done using nine females who had been taking a low-dose estrogen-containing oral pill for at least 3 months, compared to 9 females who did not take OCS.⁵ Each subject was given an oral dose of 162 mg of Caffeine. In subjects who took OCS, the elimination half-life of Caffeine was 7.88 hours, the plasma clearance was 1.05 ml/min/kg, and peak plasma concentration was 3.99 µg/ml. In subjects who did not take OCS, the elimination half-life was 5.37 hours, plasma clearance was 1.75 ml/min/kg, and the peak plasma concentration was 4.09 µg/ml.

Theophylline

The distribution of Theophylline into breast milk was studied in five women. On average, less than 10 percent of the mother's Theophylline intake was distributed into breast milk.⁶

Dermal Penetration

In Vitro

Caffeine

The follicular penetration of Caffeine was studied using a combination of the Franz diffusion cell (FDC) technique, and the follicle closing technique (FCT).²⁸ Two test substances were either 12.5 mg Caffeine (study design 1) or 2.5 g Caffeine (study design 2) dissolved in 100 ml Dulbecco's Phosphate-Buffered Saline (DPBS). Three types of skin samples were used as test barriers: a human reconstituted model, a human heat-separated model, and full-thickness human skin. Study design 1 involved the study of the permeability of both the reconstituted human epidermis model and the heat-separated human epidermis. The skin samples had a high, low, or no follicular density. These samples were exposed to the test substance for 24 hours. Samples taken from the receptor chamber were examined using high-performance liquid chromatography (HPLC). After 24 hours, the skin sample that had a normal follicular density had the lowest absorption of the three types of samples ($36.1 \pm 9.85\%$). The skin sample without follicles had absorption of $43.4 \pm 9.73\%$, and the high follicular density sample had the highest percentage of absorption ($47.1 \pm 9.10\%$).

In study design 2, the full-thickness skin membranes were mounted in the diffusion cell and subsequently exposed to the FCT. Shunts in the closed follicular pathway samples were blocked with a varnish-wax mixture. The varnish-wax mixture was also applied to the open follicular pathway samples, but only near the follicles preventing shunt blockage. Breast skin was more penetrable than abdominal skin in both types of skin samples (blocked or open follicular orifices). For example, in skin samples with artificially blocked follicular orifices, $3.6 \pm 0.59\%$ of the test substance penetrated in the epidermis of the breast skin, while $2.5 \pm 0.94\%$ penetrated into the epidermis of the abdominal skin. In both abdominal and breast skin samples, test substance penetration was higher in samples with open follicular orifices. In breast skin with open follicular orifices, $7.9 \pm 0.56\%$ of the test substance penetrated into the epidermis, while $3.6 \pm 0.59\%$ penetrated into the epidermis of blocked follicular orifice samples.

A solution containing 4 mg/mL Caffeine was applied at a dose of $50 \mu\text{L}/\text{cm}^2$ to mounted human skin.²⁷ Six hours after application, skin samples were cleaned with soap and isotonic water. Permeation was measured for 42 hours. Caffeine permeation was reported to be 24 % in cells that were not washed, and 8% in cells that were washed.

Theophylline

Human skin was used to examine the metabolism and absorption of 98% Theophylline.⁶ Absorption varied among skin samples. The lowest reported absorption was 3.6%, while the highest was 33.4%. Diffusion ranged from 2.2 - 7.7%. Approximately 0.2 - 4.6% of applied substance was metabolized, and more than 60% of the metabolites diffused through skin samples. Reported metabolites were 1,3,7-trimethyluric acid, 1,3-dimethyluric acid and 3-methylxanthine. Amount of metabolites varied per skin sample.⁶

A flow-through in vitro diffusion system was used to study percutaneous absorption of Theophylline (radiolabeled [$8-^{14}\text{C}$]) through 5 different samples of excised human skin.²⁹ Donors of the skin samples differed by age, sex, and ethnicity. Eagle's medium consisting of gentamicin sulfate and 10% fetal bovine serum was continuously perfused along the well. Receptor fluid was aerated with 95% O₂; 5% CO₂ and pumped underneath the skin's surface at a rate of 3 mL/h. The diffusion area was 1.0 cm². Skin cells were exposed to a solution of Theophylline (6.8 and 306.8 µg/cm²) and receptor fluid was collected hourly for 20 hours. The percentage of the applied dose that diffused through the skin was similar between all skin samples, with a range of 2.8-7.8%. The percentage of the applied dose that was absorbed varied greatly between skin samples (3.6 – 33.4%). The metabolites were estimated by thin-layer chromatography. Between $0.2 \pm 0.1\%$ - $4.6 \pm 0.2\%$ of the applied doses

were metabolized, and over 60% of the total formed metabolites penetrated through the skin. The metabolites that were observed were 1,3,7-trimethyluric acid, 1,4-dimethyluric acid, and 3-methylxanthine.

Human

Studies have been performed to determine the different effects of Caffeine absorption in human skin versus animal skin.³⁰ This concept was studied in human and rat skin samples. Caffeine had an overall mean maximum absorption rate of $2.24 \pm 1.43 \mu\text{g}/\text{cm}^2/\text{h}$ in human skin. The maximum absorption rate and penetration through rat skin was significantly higher than the mean values in human skin.

Caffeine

The role of hair follicles in the dermal absorption of Caffeine was studied.²⁶ A solution that contained Caffeine (2.5%), ethanol, and propylene glycol was applied to the skin of six male subjects who had not ingested Caffeine for at least 48 hours before testing. The average hair follicle density was 20-32 follicles/cm². Hair was clipped down to 0.5 mm in the 25 cm² application area of on the chests of volunteers. For the first test, a microdrop of varnish-wax mixture was applied beside each hair follicle orifice, and 2 mg/cm² of the Caffeine solution were applied to the test area of each subject for 8 h (formulation allowed to evaporate); subjects were not allowed to shower or bathe for 72 hours. A blood sample was taken at 5, 10, 20 and 30 minutes, and 1, 2, 5, 8, 24, and 72 hours after application. The same procedure was repeated in the same test areas after 3 more days of a Caffeine-free diet, but with each hair follicle orifice blocked with a microdrop of the varnish-wax mixture. Caffeine was extracted from the serum samples with dichloromethane. Serum penetration was measured by a surface ionization mass spectrometry (SI/MS) technique.

When hair follicles were left open, the average Caffeine levels in the blood 5 minutes after application were 3.75 ng/ml, and when hair follicle orifices were blocked, Caffeine was not detected in the blood until 20 minutes after application. After 20 minutes, the average amount of Caffeine detected in the blood in the blocked follicle group was 2.45 ng/ml, compared to an average blood concentration of 7.57 ng/ml in the open follicle group. The highest concentration in the open follicle group was approximately 11.75 ng/ml an hour after application, while the highest concentration in the blocked follicle group was 6.65 ng/ml at 2 hours after application. After 72 hours, no Caffeine was detected in the blood serum in either test group.

Studies have also been done to examine the effect of skin thickness and occlusion on the absorption of Caffeine.^{31,32} Human abdominal skin samples were mounted on Dianorm Teflon macro 1 cells or Franz diffusion cells. Occlusion did not have an effect on the dermal absorption of Caffeine. When Caffeine in saline was applied to skin samples varying in thickness, it was observed that the maximum flux of Caffeine was increased with decreasing thickness, but these increases were considered to be non-significant. The amount of Caffeine in the skin membrane was not affected by skin thickness.

TOXICOLOGICAL STUDIES

Acute Toxicity Studies

The acute toxicity studies summarized below are described in Table 4.

Acute dermal toxicity studies were performed in which both Caffeine⁵ and Theophylline,⁶ in olive oil, were applied under a semi-occlusive patch for 24 h to rats. The LD₅₀ was >2000 mg/kg bw for both test substances.

Numerous acute oral toxicity studies were performed with Caffeine. The lowest reported LD₅₀s in mice and rats are 127 mg/kg bw (vehicle not specified) and 192 mg/kg bw (aq.), respectively.⁵ In other species, LD₅₀s of Caffeine were 230 mg/kg bw (guinea pigs and hamsters), 224 mg/kg bw (rabbits), and 240 mg/kg bw (dogs). For Theobromine, the reported LD₅₀s in rats and dogs (vehicle not specified) were 950 and 300 mg/kg bw, respectively.⁹ For Theophylline, the lowest LD₅₀s reported for mice, rats, guinea pigs, and rabbits are 235, 225, 183, and 350 mg/kg bw, respectively.⁶

Acute inhalation studies were performed in rats on Caffeine⁵ and Theophylline⁶ mixed with a hydrophobic fumed silica. The LC₅₀ following aerosol exposure or Caffeine mixed with 2% of a hydrophobic fumed silica was 4.94 mg/L. Following a dust aerosol exposure to Theophylline mixed with 1% and 2% silica, an LC₅₀ of >6.7 mg/L was established.

Short-Term, Subchronic, and Chronic Toxicity Studies

Details of the short-term, subchronic, and chronic toxicity studies are provided in Table 5.

Repeated dose oral toxicity studies were performed with the xanthine alkaloids. In a study in which rats were given diets containing 0.5% Caffeine or 0.8% Theobromine for 7 or 8 weeks, treated rats of both groups displayed statistically significant decreases in thymus weights and vacuolar degeneration of spermatogenic cells; the effects were more severe with

Theobromine.³³ In 90-day studies in which mice and rats were dosed with Caffeine in drinking water, the no-observable-adverse effect-levels (NOAEL) were 167 and 179 mg/kg bw/day in male and female mice, respectively, and 151 and 174 mg/kg bw/day in male and female rats, respectively; the highest doses administered in these studies were 167 and 180 mg/kg bw/day to male and female mice, respectively, and ~272 and 287 mg/kg bw/day in male and female rats, respectively.⁹

In a study in which immature and mature rabbits were fed a diet containing ≥ 1.5% Theobromine for 20 or 120 days, respectively, only 25% of the immature rabbits survived until study termination in each group, including controls.³⁴ Groups 0, 1, 2 and 3 were given doses of 0, 0.5, 1 and 1.5, respectively. In mature rabbits, on day 30 of treatment, group 1 gained 6% of their original body weight, while groups 2 and 3 lost an average of 5.9 and 18.1%, respectively. At day 30, 5/8 animals died in group 2, 4/8 animals died in group 3, and 0/8 animals died in group 1. On day 120, 4/8, 7/8, and 7/8 animals died in groups 1, 2 and 3, respectively. In immature rabbits, mortality was clearly dose-dependent. Gross lesions were found on the thymus and heart. The thymus of the treated rats showed edema and extensive hemorrhages. Thymus weight was also decreased.

A 16-day gavage study was performed using mice given Theophylline in corn oil at doses as high as 400 mg/kg bw once daily.³⁵ All females and 3/5 males dosed with 400 mg/kg bw died on day 1. A similar study was performed using rats. Animals were given up to 400 mg/kg Theophylline in corn oil via oral gavage once per day for 16 days; all animals died after exposure of 400 mg/kg Theophylline given once daily and 9/10 animals died after exposure to 200 mg/kg Theophylline given twice a day. A 16-day feed study was also performed using rats given Theophylline at concentrations of up to 8000 ppm. All rats survived; the final mean body weight was statistically decreased in rats given 8000 ppm. In a study in which Theophylline was given to mice at a maximum dose of 4000 ppm for 14 weeks, statistically significant decreases in mean body weights and increases in leukocyte, segmented neutrophil, and lymphocyte counts were recorded at the 2000 and 4000 ppm dose levels. In a study in which mice were given Theophylline for 14 weeks in corn oil via oral gavage at a maximum dose of 300 mg/kg bw, a statistically significant decrease in mean body weights of male mice given 150 or 300 mg/kg bw was apparent. Two year studies were also performed. Administration of Theophylline in corn oil to mice for 2 years via oral gavage resulted in decreases in the survival, and body weights of male mice dosed with 150 mg/kg were statistically significant. In a 2 year gavage study with Theophylline in corn oil using rats, no statistically significant differences in the survival between treated and control groups were seen. Dosed rats had a statistically significant decrease in final mean body weights compared to the control group. In addition, chronic inflammation of the mesenteric arteries was increased in male rats given 75 mg/kg bw.

DEVELOPMENTAL AND REPRODUCTIVE TOXICITY STUDIES

Details of the developmental and reproductive toxicity studies summarized below are provided in Table 6.^{5,6,9,36-41}

Gross malformations and reproductive effects were reported in studies involving Caffeine, and teratogenic, fetotoxic, and maternal-toxic effects were reported in studies examining the effects of Theophylline and Theobromine in mice and rats.^{6,9} However, data from OECD SIDS suggests that the usual range of human exposure to Caffeine through food and beverage intake is far less than the threshold dose that would result in developmental, teratogenic, or reproductive effects.⁵

Studies were performed evaluating the developmental toxicity of Caffeine in mice. Mice dosed with 350 mg/kg (gestation days 8-19) and up to 39 mg/kg/d displayed no dose-related effects.^{5,37} In different studies, mice displayed reduced maternal body weight gain (100-400 mg/kg/d Caffeine; gestation days (g.d.) 6-15) a reduction of live male pups/litter, female body weight, and adjusted seminal vesicle weight (up to 88 mg/kg/d; 21-35 weeks).⁵

Multiple reproductive toxicity studies were performed using rats. Dose-dependent maternal weight gain decreases were reported when rats were dosed with 10-40 mg/kg/d (g.d. 1-20), 40-80 mg/kg/d (g.d. (1-19), 10-100 mg/kg/d (g.d. 6-20), 100 mg/kg/d (g.d. 7-19, 7-16, 16-19 or day 19), and 70-2000 ppm (g.d. 0-20).⁵ In a study where Osborne-Mendel rats were treated with up to 125 mg/kg via gavage on gestation days 0-19, 6/61 females died at the highest dose level. At the 80 mg/kg dose level, 2 litters were resorbed, and at the 125 mg/kg dose level, 4 litters were resorbed. Resorption was also noted at doses of 1500 and 2000 ppm in a different study involving rats given Caffeine in drinking water on days 0-20 of gestation. A 23% sperm radius decrease, as well as a decrease in sperm motility and velocity was observed in rats given 25 mg/kg Caffeine via oral gavage. When rats were dosed with up to 320 mg/kg/d on days 6-16 of gestation, a maternal toxicity NOAEL of 56 mg/kg bw and a teratogenicity NOAEL of 100 mg/kg bw was established.

No teratogenic effects were observed when rabbits were given up to 125 mg/kg of Caffeine via gavage on gestation days 6-16.⁵ When 40 pregnant monkeys were given Caffeine in drinking water eight weeks before pregnancy to several months after pregnancy, a dose-related increase in stillbirths, decreased maternal weight, and miscarriages were present.

In a study where rats were given up to 99 mg/kg bw/d during gestation days 6-19, no maternal toxicity was reported, but a slight decrease in fetal body weight as well as an increase in skeletal variation frequency was apparent.⁹ When rats were given 500 mg/kg bw/d for 3 or 5 days, interference of germ cell kinetics was observed, but spermatagonia was not present.

Rabbits given up to 63 mg/kg bw via feed displayed little to no maternal toxicity. In a different study, rabbits were given up to 200 mg/kg bw Theobromine via gavage on gestation days 6-29. At the 200 mg/kg dose level, 40% of the dams died, but little to no maternal toxicity was reported in rabbits given 25-125 mg/kg.

Mice given 0.2% Theophylline on gestation days 6-15 via drinking water displayed an increased percentage of resorptions/litter and a reduced number of live fetuses.³⁵ Dose-related decreases in the number of live pups/litter was also reported in a different study in which mice were given 0.3% Theophylline in feed for one week before mating and during 13 weeks of cohabitation.⁹ A statistically significant decrease in testicular weight was observed at the 300 mg/kg bw dose level in mice dosed for 13 weeks via gavage or diet. However, no effects were reported at the 150 mg/kg bw dose level. Decreases in litter size and fetal weight was noted in rats dosed with 0.4% Theophylline on gestation days 6-15.³⁵

GENOTOXICITY

Details of the genotoxicity studies summarized below are provided in Table 7.

In Vitro

Caffeine

Multiple tests were available regarding the genotoxicity of Caffeine. Ames tests performed without metabolic activation yielded positive results.⁵ Positive responses were seen at concentrations as low as 1000 µg/mL. In Ames tests performed with metabolic activation, only negative results were seen. Results were negative at doses up to 6000 µg/plate (*Salmonella typhimurium*). All chromosomal aberration studies performed without metabolic activation yielded positive results at doses as low as 194 µg/mL (Chinese hamster cell line (CHL)). Sister chromatid exchange assays performed with metabolic activation yielded both positive and negative results. Positive results were apparent in doses as low as 19 µg/mL (human xeroderma pigmentosum cell lines) and negative results were seen in doses as high as 400 mg/kg bw (Chinese hamster cells).³⁹ DNA damage and repair assays performed without metabolic activation yielded negative results in Chinese hamster V79 (V79) cells at up to 5826 µg/mL and positive results in *Escherichia coli* at doses as low as 1550 µg/mL. A DNA damage and repair assay performed with metabolic activation on *E. coli* resulted in bacterial growth and a minimal inhibitory concentration range of 187-1125 µg/plate. All micronucleus tests performed without metabolic activation resulted in positive results in doses as low as 5 µg/mL in human hepatoma cells.

The majority of cytogenetic tests performed using Caffeine yielded positive results at doses as low as 0.05 µg/mL in both human peripheral blood leukocytes and human embryonic fibroblasts. However, negative results were seen in studies at doses as high as 160 µg/mL (rat MCT1 cells). A cytogenetic test performed with metabolic activation resulted in an increase in chromosome breaks at a dose of 2.0 mg/mL in the presence of S-9. In cytogenetic studies in which the use of metabolic activation was not noted, positive and negative results were seen. In one study, Caffeine yielded positive results at a dose of 4850 µg/mL (CHL). However, Caffeine yielded negative results in two studies using HeLa cells at doses as high as 5826 µg/mL.⁴² Bacterial gene mutation assays performed without metabolic activation yielded negative results in doses as high as 20100 µg/plate (*S. typhimurium*). Positive results were observed in *E. coli* at doses as low as 6000 µg/well. Multiple mammalian cell gene mutation assays performed without metabolic activation yielded negative results in doses as high as 194 µg/mL in V79 cells. Unscheduled DNA synthesis assays performed without metabolic activation yielded negative results in doses as high as 583 in human lymphocytes.

In a human lymphoblast mutation assay, Caffeine was considered to be non-mutagenic when dosed with concentrations as high as 20 mM.⁴⁰ *S. typhimurium* cells were exposed to Caffeine with and without a drug-metabolizing system and plated after exposure at concentrations as high as 20 mM. No mutations were observed by Caffeine alone or with the drug-metabolizing system.

Theophylline

Negative and positive results were also seen in genotoxicity studies involving Theophylline. Ames tests performed with and without metabolic activation were positive and negative.³⁸ Negative results were seen at up to 20 mg/mL in human cells. However, positive results were seen at doses of 20 mg/mL in hamster cells. Cytogenetic assays performed without metabolic activation also had conflicting results, with positive results in doses as low as 500 µg/mL in human lymphocytes and negative results were seen at doses as high as 1800 µg/mL in human lymphocytes. An Ames test using *E. coli* in doses as low as 150 µg/mL produced negative results. Another bacterial gene mutation assay using *E. coli* also yielded negative results, however information on dosing was not provided. A hypoxanthine-guanine phosphoribosyltransferase (HGPRT) assay performed with and without metabolic activation produced negative results (V79 cells; up to 9 µg/mL). A mouse lymphoma assay also yielded negative results when L5178Y tk +/- cells were dosed with up to 5 mg/mL. Sister chromatid exchange assays in several cell lines (Chinese hamster Don-6, human diploid fibroblast, hamster lung fibroblasts, and human embryo fibroblasts) yielded positive results. Negative results were apparent in a sister chromatid exchange assay performed without metabolic activation using human lymphocytes at doses of up to 100 µg/mL.

In Vivo

Caffeine

A cytogenetic assay was performed in 30 rats dosed with 46 mg/kg/d via oral feed for 117 weeks.⁵ There were no statistically significant differences between treated and control rats. In a different study, 9 human volunteers were given 800 mg of Caffeine in tablet form each day. No significant increase in chromosome damage was seen. Multiple dominant lethal assays performed on mice yielded negative results at doses as high as 200 mg/kg/d. However, when mice were dosed with up to 1000 mg/kg/d for 100 or 140 days via drinking water, an increase of preimplantation loss and resorptions were seen. Positive results were seen when a micronucleus assay was performed on Chinese hamsters.⁵ Induction was apparent at the 300 mg/kg/d dose level.

A sister chromatid exchange assay was performed in Chinese hamsters given a single dose of up to 300 mg/kg Caffeine.⁵ Bromodeoxyuridine (BrdU) tablets were implanted two hours before Caffeine dosing. A slight increase in SCEs was apparent at the 150 mg/kg dose level and higher. A similar study was performed using mice. Mice were given up to 1000 mg/kg Caffeine each day for 5, 10 or 15 days. The frequency of SCEs increased in a time-dependent manner.

Theophylline

The majority of in vivo genotoxicity studies involving Theophylline yielded negative results.⁶ However, when hamsters were given up to 600 mg/kg in a sister chromatid exchange assay, positive results were noted. In a micronucleus assay in which mice were given up to 150 mg/kg Theophylline for 14 weeks via oral gavage, no increase in micronucleated cells were seen. Similar results were yielded in a micronucleus assay in which mice were given up to 850 mg/kg bw/d Theophylline in the diet for 14 weeks. Negative results were also seen in a cytogenetic assay in which rats were given up to 230 mg/kg bw/d Theophylline via oral feed for 75 weeks.

CARCINOGENICITY STUDIES

Details of the carcinogenicity studies summarized below are provided in Table 8.

IARC concluded there is *inadequate evidence* for the carcinogenicity of Caffeine in experimental animals and in humans; IARC had an overall evaluation that Caffeine is *not classifiable as to its carcinogenicity to humans*.⁹

Sprague-Dawley rats (50 rats/sex) were given Caffeine (up to 2000 ppm) for 104 weeks via drinking water.⁵ No statistically significant difference between the incidences of tumors in control and treated rats were apparent except for mammary fibroadenomas. The incidence of mammary fibroadenomas showed a significant inverse dose-response relationship. Fifty percent of the control animals displayed mammary fibroadenomas, while 26% of the highest dosed female rats showed mammary fibroadenomas.

Forty female Wistar rats were given a 0.2% (2000 mg/L) Caffeine solution as their drinking fluid for 12 months.⁴³ The average consumption of Caffeine was 13.5 g per rat. A control group of 30 rats was given untreated water. Twenty-two out of the 40 treated rats had pituitary adenomas, while 9 out of the 30 untreated rats had pituitary adenomas. Pituitary hyperplasia was seen in 5/40 treated rats, and in 1/30 untreated rats.

Three groups each of 50 male and 50 female Wistar rats were maintained on a basal diet and given either tap-water (controls), a 0.1% solution of synthetic Caffeine (purity 100%), or a 0.2% Caffeine solution as the drinking fluid for 78 weeks.⁹ Rats that survived were then given tap-water only for 26 more weeks. A total of 65/96 untreated rats had developed tumors. In the 0.1% solution group, 75/88 rats were tumor-bearing, and in the 0.2% group, 55/94 rats were tumor-bearing.

Theophylline was not carcinogenic in rats and mice when administered up to 150 mg/kg bw/d in male B6C3F1 mice and up to 75 mg/kg in male and female Fischer 344 rats.^{6,35} The National Toxicology Program (NTP) claimed there was no evidence of carcinogenic activity based on 2 year gavage studies performed on F344/N rats and B6C3F1 mice. No information regarding the carcinogenicity of Theobromine was found in the published literature.

Co-Carcinogenicity

Osborne-Mendel rats were given a diet consisting of 0.5% Caffeine, Theobromine, or Theophylline alone or with sodium nitrite.⁴⁴ In the group fed both nitrite and the xanthine alkaloids, the mortality rate was significantly increased. Food intake was decreased in Caffeine-treated rats, and a further reduction of food intake was noted in rats treated with both Caffeine and sodium nitrite. Food intake was not affected in rats treated with Theobromine alone, but rats treated with both Theobromine and sodium nitrite displayed significant decreases in intake. Rats treated with sodium nitrite only did not show an effect on food intake. Terminal mean body weights were decreased in all treated rats. The addition of sodium nitrite created a slight increase in the reduction of body weight. No neoplastic or pre-neoplastic lesions were observed.

In a different study, groups of 50 rats were given 100 mg/kg N-butyl-N-(4-hydroxybutyl)-nitrosamine (BBN).⁵ After administration of BBN, rats were given 110 mg/kg/d Caffeine for 21 months via drinking water. Groups received either

Caffeine-treated water only, Caffeine-treated water and phenacetin incorporated into their diet, or phenacetin alone. No carcinogenic potential was seen in rats given only Caffeine treated water, but an increase in tumor incidences was seen in rats given Caffeine and phenacetin combined. The increase in tumor incidences was greater in rats treated with both Caffeine and phenacetin versus rats treated with phenacetin alone.

Fischer 344 rats were given 90 mg/kg/d Caffeine via drinking water for 6 weeks.⁵ The hepatocarcinogenic potential was evaluated using groups of 12-20 rats. Rats were given one 200 mg/kg diethylnitrosamine (DEN) intraperitoneally. The test substance was administered each day 2 weeks after the DEN injection for 6 weeks. Control rats were given a DEN injection only. Carcinogenetic potential was evaluated by comparing the number and area of glutathione-S-transferase placental form positive (GST-P+) foci in the liver of treated rats with control rats. There was no increase in the number and area of GST-P+ foci in treated animals.

Tumor Promotion

BD2F1 mice were given an injection of 7,12-dimethylbenz(a)anthracene (DMBA) once a week for 6 weeks.⁴⁵ The test substance was given in doses of 250 and 500 mg/L via drinking water one week after the end of DMBA injections. C3H mice were given test substances via drinking water without the pretreatment of DMBA. In BD2F1 mice, the low dose of the test substance revealed a 20% increase of mammary carcinoma multiplicity, while the high dose revealed a 40% increase. C3H mice had an increase of mammary carcinomas of 13% at 250 mg/L Caffeine, and an increase 117% at 500 mg/L Caffeine.

OTHER RELEVANT STUDIES

Male Reproductive Impairment

Theobromine

Rats were fed Theobromine in the diet for 28 days at concentrations of 0.2-1.0%.⁹ At the 0.8% level, rats displayed severe testicular atrophy. At the 0.6% level, rats exhibited seminiferous tubular-cell degeneration. Testicular changes occurred only at lethal concentrations. A similar study was performed using a concentration of 0.6% Theobromine in the diet for 28 days. No testicular atrophy was reported.

Theobromine was fed to dogs in doses of 25, 50, 100 or 150 mg/kg/d for one year.⁹ No testicular atrophy was seen at any dose level.

Theophylline

Up to 300 mg/kg bw Theophylline was given to B6C3F1 mice via gavage for 13 weeks.⁹ Mice that were dosed with 300 mg/kg bw/d displayed a slight but statistically significant decrease in testicular weight. When dosed with 150 mg/kg bw/d or less, no effects were observed. When Fischer 344 rats were subjected to the same procedure, a statistically significant decrease in testicular weight was reported after gavage with 150 mg/kg bw/d, but no effects were reported when dosed with 75 mg/kg bw/d or less.

Holtzman rats were given Theophylline at a concentration of 0.5% for 19 weeks.⁹ Eighty-six percent of the treated rats displayed testicular atrophy. A similar study was performed in rats given 0.5% Theophylline for 14 to 75 weeks.³⁵ Bilateral testicular atrophy and atrophic changes in the epididymis, prostate gland, and seminal vesicles was noted.

DERMAL IRRITATION AND SENSITIZATION

Irritation

Animal

Caffeine

A study was performed in which a test substance containing 50% Caffeine was applied to the skin of three White Vienna rabbits under a semi-occlusive patch for 4 hours.⁵ The irritation index was 0.

Theophylline

Semi-occlusive patches containing 0.5 g of 50% aqueous Theophylline were applied to two White Vienna rabbits.⁶ Patches remained on the skin for 4 hours. After removal of patches, sites were washed and scored. Four hours after patch removal, very slight reddening of the skin was present in both rabbits. No other signs of irritation were reported. The reported irritation index was 0.0.

Doses of > 2 g/kg bw Theophylline in olive oil were applied to Wistar rats via a semi-occlusive patch for 24 hours.⁶ After patch removal, sites were washed. No deaths or substance-related effects were reported.

One male and two female White Vienna rabbits were given a 0.5 g dose of a 50% aqueous suspension of the test substance containing Theophylline under a semi-occlusive patch.⁶ Patches were kept on for four hours. After patch removal, the

exposed area was washed. Sites were scored 4, 24, 48 and 72 hours after removal. The female rabbits had slight redness four hours after patch removal. No other signs of irritation were reported.

OCULAR IRRITATION STUDIES

Caffeine

Undiluted Caffeine was applied to the eyes of three rabbits.⁵ Average irritation indices were 0.9 (corneal opacity), 0 (iritis), 1.6 (conjunctival erythema) and 0.6 (conjunctival edema). Irritation was observed in all three test subjects within the first 24 hours, and only 1 animal showed minimal corneal and conjunctival irritation by day 8.

Theophylline

Fifty-one mg of undiluted Theophylline was applied to one eye of 3 male White Vienna rabbits.⁶ Eyes were not rinsed. Tested eyes were examined 1, 24, 48 and 72 hours and 8 days after application. Minimal corneal opacity was reported for 1-2 rabbits each day, for up to 8 days. Minimal to well-defined redness and swelling was observed in the conjunctiva in all tested rabbits for up to 3 days. By day 8, only one animal showed conjunctival redness (grade 2), corneal opacity (grade 1) and keratitis. The irises of test animals were unaffected. Mean irritation indices for corneal opacity, iritis, conjunctival redness, and conjunctival swelling were 0.6, 0.0, 1.8, and 0.6 respectively.

EPIDEMIOLOGICAL STUDIES

A summary of epidemiological studies can be found in Table 9. Case-control studies regarding the carcinogenic potential of Caffeine through the intake of coffee (≥ 7 cups/day) provided no evidence of a potential breast cancer risk.^{5,9,46} Multiple studies confirmed this result. Different studies showed no or irregular association between Caffeine intake and cancer in the reproductive organs or pancreas. Cohort studies showed no correlation between risks for bladder cancer and Caffeine consumption, while a number of case-control studies showed a weak positive association between bladder cancer and coffee intake.

SUMMARY

The safety of three xanthine alkaloids in cosmetics is reviewed in this CIR safety assessment. According to the *Dictionary*, Caffeine, Theobromine, and Theophylline function as skin-conditioning agents, and Theobromine also functions as a fragrance ingredient.

According to 2018 VCRP survey data, Caffeine is reported to be used in 1033 formulations, 882 of which are leave-on products and 151 are rinse-off. Theobromine and Theophylline are reported to have a much smaller frequency of use of 5 formulations each. The results of the concentration of use survey conducted by the Council indicate Caffeine also has the highest concentration of use in a leave-on formulation; it is used at up to 6% in non-spray body and hand products.

Caffeine is readily absorbed through bodily membranes and is distributed throughout the body. Theobromine and Theophylline are both metabolites of Caffeine, and make up 14% of Caffeine's metabolism, combined. Factors such as pregnancy, oral contraceptives, and age affect the metabolism of Caffeine. All three xanthine alkaloids are metabolized by the hepatic enzyme system.

When follicular penetration of Caffeine was studied using a combination of the Franz diffusion cell and follicle closing techniques, the skin sample without follicles had absorption of $43.4 \pm 9.73\%$, and the high follicular density sample had the highest percentage of absorption ($47.1 \pm 9.10\%$). Human skin subjected to 98% Theophylline displayed a diffusion range of 2.2 – 7.7%. Approximately 0.2 - 4.6% of applied substance was metabolized, and more than 60% of the metabolites diffused through skin samples. Reported metabolites were 1,3,7-trimethyluric acid, 1,3-dimethyluric acid and 3-methylxanthine. The amount of metabolites varied per skin sample.

Studies involving acute dermal and inhalation toxicity of Caffeine and Theophylline reported low toxicity levels. The reported dermal LD₅₀ for Caffeine and Theophylline were > 2000 mg/kg bw when test substances were applied via a semi-occlusive patch. The lowest reported LD₅₀s in mice and rats are 127 mg/kg bw (vehicle not specified) and 192 mg/kg bw (aq.), respectively. In other species, LD₅₀s of Caffeine were 230 mg/kg bw (guinea pigs and hamsters), 224 mg/kg bw (rabbits), and 240 mg/kg bw (dogs). For Theobromine, the reported LD₅₀s in rats and dogs (vehicle not specified) were 950 and 300 mg/kg bw, respectively. For Theophylline, the lowest LD₅₀s reported for mice, rats, guinea pigs, and rabbits are 235, 225, 183, and 350 mg/kg bw, respectively.

When 0.5% Caffeine was given to rats for 7 or 8 weeks, a statistically significant decrease in thymus weight and vacuolar degeneration was apparent. Similar results were seen when 0.8% Theobromine was given to rats for the same duration. In 90-day studies in which mice and rats were dosed with Caffeine in drinking water, the no-observable-adverse effect-levels

(NOAEL) were 167 and 179 mg/kg bw/day in male and female mice, respectively, and 151 and 174 mg/kg bw/day in male and female rats, respectively; the highest doses administered in these studies were 167 and 180 mg/kg bw/day to male and female mice, respectively, and ~272 and 287 mg/kg bw/day in male and female rats, respectively. In 16 day gavage studies involving Theophylline, the majority of rats died after being dosed with 200 mg/kg, and all rats died when dosed with 400 mg/kg. A 16-day feed study was also performed using rats given Theophylline at concentrations of up to 8000 ppm. All rats survived; the final mean body weight was statistically decreased in rats given 8000 ppm. Administration of Theophylline in corn oil to mice for 2 years via oral gavage resulted in decreases in the survival, and body weights of male mice dosed with 150 mg/kg were statistically significant. In a 2 year gavage study with Theophylline in corn oil using rats, no statistically significant differences in the survival between treated and control groups were seen.

Gross malformations and reproductive effects were reported in studies involving Caffeine; and teratogenic, fetotoxic, and maternal-toxic effects were reported in studies examining the effects of Theophylline and Theobromine in mice and rats. The combination of Theophylline with mitomycin C greatly increased teratogenic effects, compared to Theophylline administered alone, subcutaneously. However, data from OECD SIDS suggests that the usual range of human exposure to Caffeine through food and beverage intake is far less than the threshold dose that would result in developmental/teratogenic/reproductive effects.

The majority of DNA damage and repair, cytogenetic, bacterial mutation, and sister chromatid exchange tests yielded positive results in vitro. Ames, unscheduled DNA synthesis, and mouse lymphoma tests had generally negative results. Among the mammalian studies reviewed, the majority were negative. However, some studies provided positive results when animals were dosed with amounts greater than OECD/EU recommendation of < 10mM Caffeine. Results were mainly negative in in vivo tests. Studies regarding the genotoxicity of Theobromine were limited. Among the studies, the positive results were yielded in tests that involved extremely high doses, or the absence of metabolic activation. For many studies, information regarding study procedures and supplemental information could not be found.

Multiple carcinogenicity studies were performed using mice and rats. Twenty-two out of forty rats given 0.2% Caffeine via drinking water had pituitary adenomas, while 9/30 untreated rats also had pituitary adenomas. Pituitary hyperplasia was seen in 5/40 treated rats, and in 1/30 untreated rats. When female rats were given up to 170 mg/kg bw/d and male rats were given up to 102 mg/kg bw/d for 104 weeks, tumor incidence was similar to control rats. However, mammary fibroadenomas showed a significant inverse dose-response relationship. Fifty percent of the control animals displayed mammary fibroadenomas, while 26% of the highest dosed female rats showed mammary fibroadenomas. Theophylline was not carcinogenic in rats and mice when administered up to 150 mg/kg bw/d in male B6C3F1 mice and up to 75 mg/kg in male and female Fischer 344 rats. The National Toxicology Program (NTP) claimed there was no evidence of carcinogenic activity based on 2 year gavage studies performed on F344/N rats and B6C3F1 mice.

Impairment of male reproductive organs was apparent in several studies regarding Theobromine and Theophylline. Rats fed 0.8% Theobromine in the diet for 28 days displayed testicular atrophy, and rats fed 0.6% exhibited seminiferous tubular-cell degeneration. However, in a similar study where rats were fed 0.6% Theobromine, no testicular atrophy was noted. No testicular atrophy was noted when dogs were given up to 150 mg/kg/d Theobromine for one year.

Mice dosed with 300 mg/kg bw/d Theophylline for 13 weeks via oral gavage displayed decreases in testicular weight. However, no effects were observed at the 150 mg/kg bw/d level. Testicular weight decreases were also apparent when rats were given 150 mg/kg bw/d Theophylline via oral gavage for 13 weeks. No effects were reported when rats were given 75 mg/kg bw/d or less. Eighty-six percent of rats given 0.5% Theophylline for 19 weeks in feed displayed testicular atrophy. Rats given 0.5% Theophylline for 14 to 75 weeks displayed bilateral testicular atrophy and atrophic changes in the epididymis, prostate gland and seminal vesicles.

The irritation index was 0 when White Vienna rabbits were subjected to 50% Caffeine under a semi-occlusive patch. Slight reddening was reported when White Vienna rabbits had semi-occlusive patches containing 0.5 g of 50% aqueous Theophylline applied to the skin. The reported irritation index was 0.0. Average irritation indices of 0.9 (corneal opacity), 0 (iritis), 1.6 (conjunctival erythema) and 0.6 (conjunctival edema) were recorded when undiluted Caffeine was applied to the eyes of 3 rabbits. In a similar study, 51mg of undiluted Theophylline was applied to the eyes of 3 White Vienna rabbits. Mean irritation indices for corneal opacity, iritis, conjunctival redness, and conjunctival swelling were 0.6, 0.0, 1.8, and 0.6 respectively.

The International Agency for Research on Cancer (IARC) evaluated the carcinogenicity of Caffeine in humans as inadequate evidence. Caffeine was not classifiable as to its carcinogenicity to humans.⁹ Case-control studies regarding the carcinogenicity through the intake of coffee (\geq 7 cups/day) provided no evidence of a potential breast cancer risk. Multiple studies confirmed this result. Different studies showed no or irregular association between Caffeine intake and cancer in the reproductive organs or pancreas. Cohort studies showed no correlation between risks for bladder cancer and Caffeine consumption, while a number of case-control studies showed a weak positive association between bladder cancer and coffee intake.

INFORMATION SOUGHT

CIR is seeking irritation and sensitization data (at maximum use concentrations), and inhalation toxicity data.

TABLES

Table 1. Definitions, idealized structures, and functions of the ingredients in this safety assessment^{1,CIR staff}

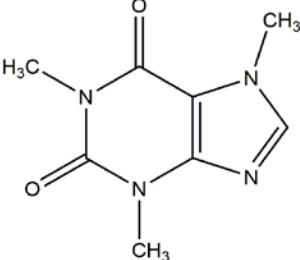

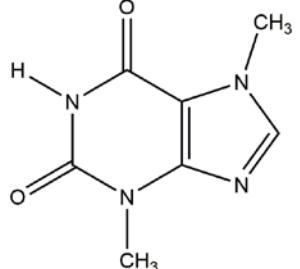

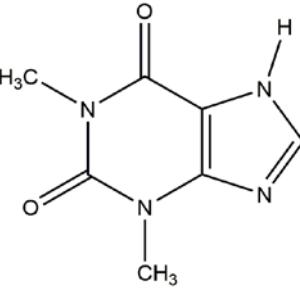

Ingredient CAS No.	Definition & Structure	Function(s)
Caffeine 58-08-2	Caffeine is the heterocyclic organic compound that conforms to the formula: 	Fragrance Ingredients; Skin-Conditioning Agents-Miscellaneous
Theobromine 83-67-0	Theobromine is the heterocyclic compound that conforms to the formula: 	Fragrance Ingredients; Skin-Conditioning Agents-Miscellaneous
Theophylline 58-55-9	Theophylline is the xanthine derivative that conforms to the formula: 	Skin-Conditioning Agents-Miscellaneous

Congestion, bloody ulcers in the glandular stomachs and hyperemia was discovered in the rats that died.	⁵
Theophylline; test substance mixed with 1% and 2% of a hydrophobic fumed silica	Rat	10	aerosol	2.39, 6.7 mg/L; rats were exposed to a dust aerosol of the test substance using a head-nose inhalation system for 4 hours	>6.7 mg/L; No deaths occurred	⁶

NR = Not Reported

Table 5. Repeated Dose Toxicity Studies

Ingredient	Animals/Group	Study Duration	Vehicle	Dose/Concentration	Results	Reference
ORAL						
Caffeine	B6C3F1 mice (12/sex)	90 days	drinking water	21.4, 43.6, 85.4, 130.5, 167.4 mg/kg bw/d (male); 24.6, 46.6, 87.9, 134.4, 179.4 mg/kg bw/d (female)	Body weight was statistically significantly decreased, but was not dose-dependent. Significant decreases in the levels of serum amylase (1500 ppm, male and female), serum aspartate aminotransferase (375 ppm, female), and alanine aminotransferase (1500 ppm, females) were present. Water consumption was decreased in the higher dosed animals. No gross morphology or irregular microscopic findings were observed. NOAEL male: 167.4 mg/kg bw/d NOAEL female: 179.4 mg/kg bw/d	⁵
Caffeine	male Sprague-Dawley rats	7 or 8 weeks	feed	0.5%	Statistically significant decreased in body weight and food consumption was noted. Decreases in thymus weight were apparent. Treated rats displayed vacuolar degeneration of spermatogenic cells.	³³
Caffeine	Fischer 344 rats (12/sex)	90 days	drinking water	19.7, 41.8, 85.4, 151, 271.9 mg/kg/d (male); 23.1, 51, 104.2, 174.2, 287 mg/kg/d (female)	Body weight gain in all groups was decreased in all dose levels, however the effect was only statistically significant in the highest dose only. In animals given the highest dose, a body weight reduction of 26% and 20% was observed in males and females, respectively. Water consumption was decreased in the high dosed groups. Microscopic evaluation of sex organs revealed no difference between treated and control rats. NOAEL male: 151 mg/kg bw/d NOAEL female: 174.2 mg/kg bw/d	⁵
Theobromine	male Sprague-Dawley rats	7 or 8 weeks	feed	0.8%	Statistically significant decreases in body weight and food consumption were noted. Decreases in thymus weight were apparent. Treated rats displayed severe testicular atrophy and spermatogenic cell degeneration/necrosis.	³³
Theobromine	8 rabbits/group	20 days (immature rabbits) or 120 days (mature rabbits)	feed	0, 0.5, 1, 1.5%	Mature rabbits dosed for 120 days displayed a dose-dependent increase in the severity of lesions in the thymus, heart and testes. For rabbits given 1 or 1.5% Theobromine in the diet, 1/8 survived the duration of 120 days. 4/8 mature rabbits exposed to 0.5% Theobromine in the diet survived. Statistically significant decreases in weight gain were present in a dose-dependent manner. In rabbits that died, sever pulmonary congestion, slight to moderate hydropericardium and scattered foci of myocardial necrosis were present. Congestion of the capillaries and intraalveolar oedema was apparent. Degeneration of the heart was seen, and in severe cases, fragmentation of the fibres associated with macrophage infiltration was apparent. Damage to the seminiferous tubules was also noted. In immature rabbits dosed, mortality was apparent in a dose-dependent manner. Gross lesions were similar to those that appeared in mature rabbits. The thymus of treated animals showed oedema and widespread haemorrhages.	³⁴
Theophylline	B6C3F1 mice (5 male/5 female per group)	16 day (gavage)	corn oil	0, 12.5 (twice daily), 25 (once daily), 50 (once daily), 50 (twice daily), 100 (once daily), 200 (once daily), 200 (twice daily), 400 (once daily) mg/kg bw	Three out of five males and 5/5 females dosed with 400 mg/kg once daily died on day 1. No statistically significant decreases in body weight were found. No other findings were reported.	³⁵

Table 5. Repeated Dose Toxicity Studies

Ingredient	Animals/Group	Study Duration	Vehicle	Dose/Concentration	Results	Reference
Theophylline	B6C3F1 mice (10 male/10 female per group)	14 week (gavage)	corn oil	0, 75, 150, 300 mg/kg bw	Three males and 10 females given 300 mg/kg, one 75 mg/kg male, and one control female died before study completion. The decrease in mean body weights of male mice given 150 and 300 were statistically significant. The increase in mean cell volume and mean cell hemoglobin of male mice dosed with 300 mg/kg was also statistically significant. Slight dose-dependent increases in the incidences of mesenteric periarteritis in both sexes were apparent. No other findings were reported.	³⁵
Theophylline	B6C3F1 mice (10 male/10 female per group)	14 week (feed)	feed	0, 1000, 2000, 4000 ppm	Decreases in mean body weight were statistically significant in all mice. One animal per sex died before completion of the study. The increase in leukocyte, segmented neutrophil, and lymphocyte counts of male mice dosed with 4000 ppm was statistically, significantly increased compared to controls. Increases in the leukocyte and segmented neutrophil counts of female mice dosed with 2000 and 4000 ppm was statistically greater than controls. Slight dose-dependent increases in the incidences of mesenteric periarteritis in both sexes were apparent. No other findings were reported.	³⁵
Theophylline	B6C3F1 mice (50 male/50 female per group)	2 year (gavage)	corn oil	0, 15, 50, 150 (male); 0, 7.5, 25, 75 (female)	The decrease in the survival and body weights of 150 mg/kg males were statistically significant. Decreases in the final body weights of 150 mg/kg males, and 25 and 75 mg/kg females were also statistically significant. No treatment-related increases in the incidence of nonneoplastic lesions or neoplasms were reported. There were decreased incidences of hepatocellular adenomas compared to control mice. Male mice showed a pattern of nonneoplastic liver lesions along with silver-staining helical organisms in the liver (<i>Helicobacter hepaticus</i>). These lesions were significantly more prominent in control males compared to males treated with 150 mg/kg/	³⁵
Theophylline	F344 N rats (5 male/5 female per group)	16 day (gavage)	corn oil	0, 12.5, (twice daily) 25 (once daily), 50 (once daily), 50 (twice daily), 100 (once daily), 200 (once daily), 200 (twice daily), 400 (once daily) mg/kg bw	All rats that received 400 mg/kg once daily died, and all but one female rat receiving 200 mg/kg twice daily died. Final mean body weights and body weight gains of groups receiving Theophylline twice per day were similar to those receiving the same doses once per day. Body weight gains of males receiving 100 or 200 mg/kg and of females receiving 50-200 mg/kg were less than the weight gain of the control animals. Uterine weights of females that were dosed with 100 or 200 mg/kg once per day were significantly less than females receiving 50 mg/kg daily. Uterine atrophy was apparent in 3 females receiving 200 mg/kg twice per day. Periarthritis was observed in 2 male and 2 female animals dosed with 400 mg/kg twice daily. No other findings were reported.	³⁵
Theophylline	F344 N rats (5 male/5 female per group)	16 days (feed)	feed	0, 500, 1000, 2000, 4000, 8000 ppm	All rats survived. The decrease of final mean body weight was statistically significant in rats given 8000 ppm. Testis weights were statistically significantly decreased in male rats given 4000 ppm. All rats survived until completion of the study. The incidence of uterine hypoplasia was observed in treated females.	³⁵
Theophylline	F344 N rats (10 male/10 female per group)	14 week (feed)	feed	0, 1000, 2000, 4000 ppm	The increase in the final mean body weights in rats given 1000 ppm compared to the control group was statistically significant. Segmented neutrophil counts in all dosing groups were significantly greater than the control group. Kidney weight was increased in rats given 4000 ppm. A dose -related, statistically significant increase in the severity of nephropathy in males and incidences of mesenteric and/or periarthritis in males and females was apparent.	³⁵

Table 5. Repeated Dose Toxicity Studies

Ingredient	Animals/Group	Study Duration	Vehicle	Dose/Concentration	Results	Reference
Theophylline	F344 N rats (50 male/50 female per group)	2 year (gavage)	corn oil	7.5, 25, 75 mg/kg bw	No statistically significant differences in survival between treated and control groups. Dosed rats had final mean body weights that were statistically, significantly lower than the control group. No statistically significant increases in the frequency of neoplasms were found. Chronic inflammation of the mesenteric arteries was increased in males given 75 mg/kg bw. Dose-related negative trends in the incidence of mammary gland fibroadenomas and fibrodenomas or carcinomas combined in females.	³⁵

NOAEL= no-observed-adverse-effect-level

Table 6. Developmental and Reproductive Toxicity Studies

Test Article	Animals/Group	Vehicle	Dose/Concentration	Procedure	Results	Reference
ORAL						
Caffeine	CD-1 mice (20 pairs of animals/generation)	Water	0, 4-5, 12-18, 25-39 mg/kg/d	A population of mice was bred for four generations, and administrated Caffeine via drinking water. Twenty pairs of mice were bred in each generation.	No dose-related effects on fertility, sexual maturity, litter size, offspring weight, sex ratio, or abnormalities were observed.	³⁷
Caffeine	CD-1 mice; 40 animals/sex for the control and 20 animals/sex for the treated groups	Water	0, 22, 44, 88 mg/kg/d	Animals were given drinking water containing Caffeine during a 7 day premating period and during the 100 day cohabitation period. A crossover mating trial was then performed.	F0: no effect on body weight, alopecia in 55% on mice at 44 mg/kg/d and 50% of mice at 88 mg/kg/d; the number of live pups/litter decreased as Caffeine dosage increased; male body weight was reduced by 8%, no change in female body weight	⁵
Caffeine	CD-1 Mice (# of animals not stated)	Water	350 mg/kg	Mice were dosed once daily on days 8-18 of gestation.	No effect on the average number of litters per pair or mean number of pups/litter was observed. There was a 20% reduction of live male pups/litter. The amount of pups born alive decreased as Caffeine dosage increased. No differences between control and tested groups in mating and fertility indices. Female body weight decreased by 5%. Testis weight dropped by 7% and adjusted seminal vesicle weight dropped by 12%.	⁵
Caffeine	CD-1 Mice (# of animals not stated)	NR	50, 100, 250, 400 mg/kg/d (# of animals not stated)	Mice were given daily doses via gavage on days 6-15 of gestation.	No difference was noted between the control group and treated mice regarding embryonic resorption, growth, skeletal development, or terata. Supernumerary ribs were the only observed fetal affect with a linear inverse relationship between maternal body weight gain during gestation.	⁵
Caffeine	Osborne-Mendel Rat (61 rats/group)	Water	6, 12, 40, 80, 125 mg/	Rats were treated by gavage each day on days 0-19 of gestation.	Reduced maternal body weight gain was reported at the 100 mg/kg/d level. Developmental effects on fetal weight and ossification were observed at the 250 mg/kg/d level and higher.	⁵
					Six females died at the 125 mg/kg dose level. A statistically significant decrease in weight gain as well as food consumption was observed in treated animals compared to controls. Two litters were resorbed at the 80 mg/kg dose level and 4 litters were resorbed at the 125 mg/kg dose level. Statistically significant decreased in fetal weight and	⁵

Table 6. Developmental and Reproductive Toxicity Studies

Test Article	Animals/Group	Vehicle	Dose/Concentration	Procedure	Results	Reference
Caffeine	CD rats (12 rats/group)	Water	10, 20, 40 mg/kg d	Rats were administered the test substance via gavage on days 1-20 of gestation, and allowed to litter.	crown-rump length was reported at 40 mg/kg. Ectrodactyly was seen at the dose levels of 80 and 125 mg/kg. At this dose level, skeletal ossification problems such as misshapen centra, missing centra, reduced dorsal arch, reduced pubis, missing hind phalanges, reduced metacarpals, and reduced metatarsals were also seen.	⁵
Caffeine	Sprague-Dawley Rat (8 animals/sex/dose)	Water	0, 12.5, 25, 50 mg/kg	Rats were given Caffeine in deionized water via gavage for 28 days and allowed to cohabitare.	No consistent effects were reported, however, Caffeine caused a reduced maternal weight gain at all three dose levels.	⁵
Caffeine	CD rats (20 rats/group)	Water	0, 40, 80 mg/kg bw	Rats were given doses via gavage on days 1-19 of gestation.	Pup weight decreased by 7, 7, and 8% in the 12.5, 25, and 50 mg/kg dose groups, respectively. The average sperm radius was decreased by 23 and 26% in the 25 and 50 mg/kg groups, respectively. Sperm motility was reduced by 4%, and sperm velocity was reduced by 9%. Organ weight was decreased in all groups.	⁵
Caffeine	Rat (# of animals not stated)	Water	10, 100 mg/kg	Pregnant rats were given either a single bolus, or 4 separate boluses, containing Caffeine for 15 days via gavage on days 6-20 of gestation.	At both dose levels, a statistically significant reduction of maternal weight gain was apparent. However, this did not have an effect on the rate of prenatal death or malformation. Fetal weight was significantly reduced in the high dosed-group.	⁵
Caffeine	Osborne-Mendel Rats (Sixty females were mated in the control and lowest dose groups and 30 females were mated for the mid and high dose group)	Water	180, 360, 700 ppm	Rats were given Caffeine in drinking water continuously on days 0 to 20 of gestation. Animals were killed on either gestation day 20, postnatal day 0 or postnatal day 6.	Caffeine treated animals displayed a dose-dependent decrease in maternal body-weight gain during the first week of treatment. During the second week of treatment, all groups showed similar weight gain patterns, however, rats treated with the high dose had lower final body weights than control rats and low-dose treated rats. Increases in late resorptions, retarded ossification of the fetal skeleton, and incidences of malformed fetuses were present in the group given 100 mg/kg Caffeine once a day. Significant decreases in fetal weight and length was observed in groups treated with 100 mg/kg Caffeine once daily or 25 mg/kg Caffeine 4x daily.	⁵

Caffeine	Osborne-Mendel Rats (61 females/group)	Water	70, 180, 360, 700, 1000, 1500, 2000 ppm	Rats were given Caffeine continuously in the drinking water on days 0-20 of gestation. Dams were killed on day 20 of gestation.	The decrease of maternal food and water consumption was statistically significant at doses of 1000 ppm and higher. Maternal body weight gain was statistically significantly decreased at doses of 1000 ppm and higher. At doses of 1500 and 2000 ppm, decreased implantation efficiency, increased resorptions, and decreased mean number of viable fetuses was observed.	⁵
Caffeine	Rabbits (# of animals not stated)	Water	14, 40, 125 mg/kg	Rabbits were given test substance via gavage or drinking water.	No teratogenic effects were observed.	⁵
Caffeine	Monkey (40 female monkeys)	Water	10-15, 25-30 mg/kg/d	Forty pregnant monkeys were continuously given Caffeine in drinking water eight weeks before pregnancy to several months after pregnancy.	Dose-related increases in stillbirths, miscarriages and decreased maternal weight were present. Infant body weights were reduced over the first 30 days in males, but the deficits were reversible and not evident after one year of age. These effects were seen at all dose levels.	⁵
Theobromine	Sprague-Dawley Rats (# of animals not stated)	NR	53 or 99 mg/kg bw d	Rats were fed diets containing theobromine on gestation days 6-19	No maternal toxicity reported; slight decrease in fetal body weight and increase in skeletal variation frequency at high dose. No other developmental/reproductive toxicity information was noted.	⁹
Theobromine	New Zealand white rabbits (# of animals not stated)	feed	21, 41,63 mg/kg bw	Rabbits were diets containing Theobromine.	Little or no maternal toxicity was observed. A fetal body weight and increase in the frequency of skeletal variations was observed at the 41 and 63 mg/kg bw levels. No other developmental/reproductive toxicity information was noted.	⁹
Theobromine	New Zealand white rabbits (# of animals not stated)	NR	up to 200 mg/kg bw	Rabbits were given test substance via gavage on gestation days 6-29.	40% of rabbits receiving 200 mg/kg died; little or no maternal toxicity was observed at the lower doses; decreases in fetal body weight and an increase in malformations was seen at doses of 125 or 200 mg/kg.	⁹
Theophylline	CD-1 Mice (# of animals not stated)	Water	0.2%	Mice were given 0.2% Theophylline in drinking water on gestation days 6 through 15.	An increased percentage of resorptions per litter and reduced number of live fetuses/fetal weight as well as decreases in gravid uterine weight were noted. No other developmental/reproductive toxicity information was noted.	³⁵
Theophylline	Swiss CD-1 Mice (# of animals not stated)	Feed	0.075, 0.15, 0.30%	Mice were given Theophylline in the diet for one week before mating and during 13 weeks of cohabitation. Litters were removed one day after birth, except for one litter which was raised for 21 days.	A dose-related decrease in the number of live pups/litter was reported in the high-dose groups. A statistically significant decrease in live pup weight as well as number of litters/breeding pairs was also reported in the high-dose groups. No other developmental/reproductive toxicity information was noted.	⁹
Theophylline	CD Rats (# of animals not stated)	Water	0.4%	Rats were dosed with drinking water containing 0.4% Theophylline on gestation days 6 to 15	A reduction of litter size and fetal weight was noted, but no increases in malformations. No other developmental/reproductive toxicity information was noted.	³⁵

NOAEL= no-observed-adverse-effect-level; NR = Not Reported

Test Article	Concentration/Dose	Test System	Procedure	Results	Reference
Caffeine	5, 50, 500 µg/mL	Human hepatoma (Hep-G2) cells	Micronucleus test without metabolic activation, incubation for 24 hours, 1000 cells/dose level scored	positive, dose-dependent increase in micronuclei frequency	⁵
Caffeine	0.05, 0.1, 0.25, 0.5, 1.0 µg/mL	Human peripheral blood leukocytes	Cytogenetic assay without metabolic activation	positive, chromosome damage seen at the DNA-synthesis phase, S-phase most sensitive, G1 and G2 not affected	⁵
Caffeine	0.05, 0.1, 0.25, 0.5, 1.0 µg/mL	Human embryonic fibroblasts	Cytogenetic assay without metabolic activation	positive , chromosome damage seen at DNA-synthesis phase, S-phase most sensitive, G1 and G2 not affected; gaps and breaks, no exchanges observed	⁵
Caffeine	5, 10, 25, 50, 75, 100 µg/mL	Human lymphocytes	Cytogenetic assay without metabolic activation, activation with S-9 mix made from animal liver homogenate	negative	⁵
Caffeine	40, 60, 80, 120, 140, 160 µg/mL	Human HeLa cells	Cytogenetic assay without metabolic activation	positive, significant and dose-dependent increase in terminal break frequency at concentrations of 40 µg/mL and higher	⁵
Caffeine	40, 60, 80, 120, 140, 160 µg/mL	Rat MCTI cells	Cytogenetic assay without metabolic activation	negative, only minimal effects after 1-4 weeks of treatment	⁵
Caffeine	250, 500, 750 µg/mL	Human lymphocytes	Cytogenetic assay without metabolic activation	positive	⁵
Caffeine	252, 505, 757 µg/mL	Human diploid fibroblasts	Cytogenetic assay without metabolic activation, incubation with test substance for 24 hours, colcemid added 24 hours later, 200 metaphases/dose scored	positive, mitotic index reduction of 58% at the 252 µg/mL dose level with significant clastogenicity, no exchanges observed	⁵
Caffeine	485, 971 µg/mL	Human lymphocytes	Cytogenetic assay without metabolic activation	positive, increased frequency of chromatid breaking and decreased G2 duration in X-ray irradiated and nonirradiated cells	⁵
Caffeine	1.0, 1.5, 2.0 mg/mL	Human diploid fibroblasts	Cytogenetic assay with and without metabolic activation, activation with S-9 mix made from rat liver homogenate, incubated with test substance, colcemid added 24 hours later, 100 metaphases/dose scored	positive, increase in chromosome breaks at high concentration in presence of S-9, no exchanges observed	⁵
Caffeine	5, 10 or 20 µg/mL	HeLa cells	Cytogenetic assay, cultures exposed for 6 and 9 weeks, cells examined twice a week	negative, no breaks or growth effects reported	⁴²
Caffeine	583, 1942, 5826 µg/mL	HeLa cells	Cytogenetic assay, suspended in culture for 7-11 days	negative; no chromatid break increase was observed when cells were exposed to 5 and 20 µg/mL of Caffeine.	⁴²
Caffeine	4850 µg/mL	CHL	Cytogenetic assay	positive result observed at 4850 µg/mL dependent on temperature, but not ATP content	⁵
Caffeine	up to 1940 µg/plate	<i>E. coli</i> K12	Bacterial gene mutation assay with and without metabolic activation, activation with S-9 mix made from mouse liver homogenate	negative	⁵
Caffeine	194 µg/mL	V79	Mammalian cell gene mutation assay without metabolic activation	negative, no induction of ouabain-resistant mutants was induced	⁵
Caffeine	97, 146, 194, 388, 583 µg/mL	Human lymphocytes	Unscheduled DNA synthesis without metabolic activation, lymphocytes obtained from healthy donors and patients with systemic lupus erythematosus (SLE)	negative, no inhibition of DNA repair in normal lymphocytes, no further reduction of DNA repair in SLE cells	⁵

Table 7. Genotoxicity studies

Test Article	Concentration/Dose	Test System	Procedure	Results	Reference
Caffeine	0, 5, 10, 15, 20 mM	Human lymphoblast lines MIT-2 and HH-4	Human lymphoblast mutation assay; cell lines were maintained in RPMI 1640 supplemented with either 10% or 15% fetal calf serum; after treatment, cells centrifuged; 4000 cells were plated and incubated for 2 weeks	At significantly toxic concentrations, Caffeine was not mutagenic.	⁴⁰
Caffeine	0, 5, 10, 15, 20 mM	<i>S. typhimurium</i>	Cells were exposed with and without a drug-metabolizing system; cells were resuspended in phosphate-buffered solution and plated after exposure	No mutations were observed by Caffeine alone or with the drug-metabolizing system.	⁴⁰
Caffeine	NR	<i>S. typhimurium</i>	5 strains of Salmonella were subjected to a microsome assay with and without metabolic activation	negative	^{41,48}
Theophylline	1-10,000 µg/plate	<i>S. typhimurium</i> TA97 _a , TA100, TA102, TA104	Ames test with and without metabolic activation, activation with S-9 mix made from rat liver homogenate	negative, very weak mutagenic activity (factor up to 1.5) observed in TA104 and TA102 in presence of S-9	⁶
Theophylline	100, 333, 1000, 3333, 10000 µg/plate	<i>S. typhimurium</i> TA97, TA98, TA100, TA1535	Ames test with and without metabolic activation, activation with S-9 mix made from liver homogenate of rats and hamsters	negative	⁶
Theophylline	10 mg/mL	<i>S. typhimurium</i> TA100, TA98	Ames test with and without metabolic activation, test substance consisted of Theophylline dissolved in distilled water, concentrations of 0.01-1 mg/petri dish tested	positive; the higher concentrations had negative effects on bacteria; a weak mutagenic effect was evident in TA 100 without the S9 fraction, however mutagenicity was not present when the same bacteria was tested with Theophylline and the S9 fraction; bacterial strain TA 98 showed no mutagenic effects	³⁸
Theophylline	20 mg/mL	Hamster cells	Ames test with and without metabolic activation, test substance consisted of Theophylline dissolved in distilled water	positive; weak mutagenic effect was seen in the absence of S9 cells in hamster cells; in the presence of S9, a decreased level of spontaneous mutation was evident	³⁸
Theophylline	20 mg/mL	Human cells	Ames test with and without metabolic activation, test substance consisted of Theophylline dissolved in distilled water	negative, no DNA damage observed	³⁸
Theophylline	NR	Chinese hamster Don-6 cells and human diploid fibroblasts	Sister chromatid exchange assay without metabolic activation	positive	⁶
Theophylline	1, 10, 100 µg/mL	Human lymphocytes	Sister chromatid exchange assay without metabolic activation	negative	⁶
Theophylline	18, 90, 360 µg/mL	CHO	Sister chromatid exchange assay without metabolic activation, incubated with test substance for 26 hours or 46 hours	positive, number of SCEs slightly increase (factor up to 2.8), potentiated toxic effects of methylNitrosurea and reduced cloning efficiency of cellular growth rate	⁶
Theophylline	13 mg/mL	HeLa cells	Cytogenetic assay without metabolic activation, incubated with 1.3% solution of test substance for 1 hour and fixed after 30 hours	positive, chromatid breaks: 68/2776 in treated cells (2.4%) and 3/3208 in control cultures (0.1%)	⁶

Table 7. Genotoxicity studies

Test Article	Concentration/Dose	Test System	Procedure	Results	Reference
Theophylline	18, 180, 1800 µg/mL	Human lymphocytes	Cytogenetic assay without metabolic activation, incubated with test substance for 72 hrs, 1000 cells/culture examined	negative, mitotic rate was 16% of control at low concentration, no mitosis seen at mid and high concentration; no chromosome damage observed	⁶
Theophylline	1, 10, 100 µg/mL	Human lymphocytes	Cytogenetic assay without metabolic activation	positive	⁶
Theophylline	250, 500, 750 µg/mL	Human lymphocytes	Cytogenetic assay without metabolic activation	positive, increase in breaks at dose of 500 µg/mL and above, mitotic indices reduced at 500 µg/mL and above	⁶
Theophylline	577, 1135 µg/mL	FM3A cells	Cytogenetic assay without metabolic activation, cells incubated with test substance for 24 and 48 hours	positive; the low dose produced 20 aberrant metaphases after 24 hours and 68% aberrant metaphases after 48 hours; high dose produced 46 and 56% aberrant metaphases after 24 and 48 hours, respectively	⁶
Theophylline	0, 100, 150, 200 µg/mL	Human lymphocytes	Cytogenetic assay	positive	⁶
Theophylline	510, 555, 600 µg/mL	CHO	Cytogenetic assay with and without metabolic activation, activation with S-9 mix made from liver homogenate of rats,	negative	⁶
Theophylline	NR	<i>E. coli</i> 15+m-	Bacterial gene mutation assay without metabolic activation	positive	⁶
Theophylline	150 µg/mL	<i>E. coli</i>	Bacterial gene mutation assay	positive	⁶
Theophylline	5, 7, 9 µg/mL	V79	HGPRT assay with and without metabolic activation	negative	⁶
Theophylline	up to 5 mg/mL	L5178Y tk +/- cells	Mouse lymphoma assay	negative, treatments greater than 24 hours produced weakly positive results	⁶
IN VIVO					
Caffeine	46 mg/kg/d	Rat (oral feed); 30 rats	Cytogenetic assay, 117 weeks of treatment	negative, no significant difference between treated and control rats	⁵
Caffeine	800mg/daily	Human (tablet); 9 volunteers	Chromosomal damage assay; volunteers treated for 4 weeks, 200 mg 4x a day	negative, no significant increase in chromosome damage, single exposure of cells at the 48 h time produced gaps and breaks in the 250-750 µg/mL range	⁵
Caffeine	4, 13, mg/kg	Mouse (drinking water); 5 male mice/group	Dominant lethal assay, 16 week exposure, each male mated to five females a week for 7 weeks	negative, litter size and fertility unaffected	⁵
Caffeine	3.6, 13.4, 49, 122 mg/kg/d	Mouse (drinking water)	Dominant lethal assay, 8 weeks of exposure	negative	⁵
Caffeine	90 mg/kg, 112 mg/kg	Mouse (oral)	Dominant lethal assay, 3 (112 mg/kg) or 6 weeks (90 mg/kg)	negative	⁵
Caffeine	90 mg/kg, 112 mg/kg	Mouse (drinking water, gavage); 50 mice/group	Dominant lethal assay, 8 weeks (112 mg/kg) drinking water or 5 days (90 mg/kg) gavage; administered drinking water, 10 male mice administer i.p. injection	negative, no mutagenic induction of dominant lethals, preimplantation losses, or depression of female fertility observed	⁵
Caffeine	200 mg/kg d (drinking water), 168-240 mg/kg (i.p.)	Mouse (drinking water, i.p.)	Dominant lethal assay	negative	⁵
Caffeine	50, 100, 200, 400, 600, 800, 1000 mg/kg/d	Mouse (drinking water)	Dominant lethal assay, exposure for 100 or 140 days, mated to untreated females for three weeks or more	positive, increase of preimplantation loss and resorptions	⁵

Table 7. Genotoxicity studies

Test Article	Concentration/Dose	Test System	Procedure	Results	Reference
Caffeine	NR	Mouse (drinking water); 6 mice/group	Dominant lethal assay, 254-550 days of exposure, each male mated with five females each week for 8 weeks	negative, no significant increase in embryonic deaths, males given highest doses produced less pregnancies	⁵
Caffeine	1000 mg/kg/d	Mouse (drinking water); 3 mice/group	Sister chromatid exchange assay, exposure period of 5, 10, or 15 days, given test substance; colchicine and BrdU injections given at 19 and 2 hours before mice were killed; 25 metaphase/animal scored	positive, SCE/cell frequency increase in exposure time-related manner	⁵
Caffeine	0, 20, 100, 200, 400 mg/kg	Chinese hamster (gavage)	Sister chromatid exchange assay, given 2 doses within 24 hours in an aqueous solution	positive	⁵
Caffeine	0, 45, 75, 100, 300 mg/kg/d	Chinese hamster (gavage); 8 hamsters/group	Micronucleus assay, given 1 or 2 gavage doses of test substance in water, bone marrow removed from femur and studied	positive, induction seen at highest dose level	⁵
Caffeine	0, 45, 75, 150, 300 mg/kg	Chinese hamster (gavage); 8 hamsters/group	Sister chromatid exchange assay, given single dose , BrdU tablets implanted at 2 h prior to dosing; animals injected with 0.02 mg vincristine and killed 3.5 hours later	positive, slight increase in SCE at 150 mg/kg and higher	⁵
Theophylline	75, 150 300 or 75, 150 mg/kg bw/d	Mouse (gavage); 7-10 mice/sex/group	Micronucleus assay, 14-week exposure	negative, no increase in micronucleated cells	⁶
Theophylline	175, 400, 800 or 225, 425, 850 mg/kg bw/d	Mouse (oral feed); 10 mice/sex/group	Micronucleus assay, 14-week exposure	negative, no increase in micronucleated cells observed	⁶
Theophylline	230 mg/kg bw/d	Rat (oral feed); 6 treated and 5 untreated rats	Cytogenetic assay, 75 week exposure	negative	⁶
Theophylline	0, 30, 75, 150, 225, 300, 450, 600 mg/kg	Hamster (gavage)	Sister chromatid exchange assay, implantation of BrdU tablets	positive	⁶

BrdU = Bromodeoxyuridine; CHL = Chinese Hamster Cell Line; CHO = Chinese Hamster Ovary Cells; *E. coli* = *Escherichia coli*; HeLa = Henrietta Lacks (uterine cell variety; deceased patient); HGPRT = Hypoxanthine-Guanine Phosphoribosyl Transferase; MCT1 = Monocarboxylate Transporter 1 Cells; NR = Not Reported; SCE = Sister Chromatid Exchange; SHE = Syrian Embryo Cells; *S. typhimurium* = *Salmonella typhimurium*

Table 8. Carcinogenicity studies

Ingredient	Animal (#/group)	Dose/Vehicle	Procedure	Results	Reference
Caffeine	Wistar Rats (40 females; 30 controls)	0.2% (2000 mg/L)	A Caffeine solution was given to the rats as their drinking fluid for 12 months. The average consumption of Caffeine was 13.5 g per rat. The control rats were given untreated water.	Twenty-two out of the 40 treated rats had pituitary adenomas, while 9 out of the 30 untreated rats had pituitary adenomas. Pituitary hyperplasia was seen in 5/40 treated rats, and in 1/30 untreated rats.	⁴³
Caffeine	Wistar Rats (50/sex/group)	0.1%, 0.2%	Rats were maintained on a basal diet and given either tap-water (controls), a 0.1% solution of synthetic Caffeine (purity 100%), or a 0.2% Caffeine solution as the drinking fluid for 78 weeks	Rats that survived were then given tap-water only for 26 more weeks. A total of 65/96 untreated rats had developed tumors. In the 0.1% solution group, 75/88 rats were tumor-bearing, and in the 0.2% group, 55/94 rats were tumor-bearing.	⁹
Caffeine	Sprague-Dawley Rats (50 rats/sex)	12, 26, 49, or 102 mg/kg bw/d (males); 15, 37, 80, or 170 mg/kg bw/d (females)	Caffeine was given to Sprague-Dawley rats in drinking water for 104 weeks.	Mortality was slightly increased in males dosed with 102 mg/kg. Decreased body weight was apparent in both sexes at the higher dose levels. No significant differences were apparent in control and treated animals for tumors except for mammary fibroadenomas. The incidence of mammary fibroadenomas showed a significant inverse dose-response relationship. Fifty percent of the control animals displayed mammary fibroadenomas, while 26% of the highest dosed female rats showed mammary fibroadenomas.	⁵

Ingredient	Animal (#/group)	Dose/Vehicle	Procedure	Results	Reference
Theophylline	B6C3F1 Mice	15, 50, 150 mg/kg bw/d (male); 7.5, 25, 75 mg/kg bw/d (female)	Mice were given of test substance in corn oil via gavage, 5 days a week, for 2 years.	Males given high doses experienced a high mortality rate. Mean body weights at the end of the two year period were greatly increased in high dose males and females, and mid dose females. An increase in neoplasms and neoplastic lesions was not observed. Frequencies of hepatocellular carcinomas and adenomas were decreased in treated mice. Low and mid dose treated male mice had a combination of lesions (non-neoplastic) and silver staining helical organisms in the liver. High dose treated male mice had a greatly reduced number of liver lesions. Authors attributed the increase in hepatocellular neoplasms in male mice to <i>Helicobacter hepaticus</i> infection when mice were also affected by hepatitis. The authors found it difficult to interpret the decreased incidence of liver neoplasms in high dose treated male mice.	⁶
Theophylline	Fischer 344 Rats (50/sex)	0, 7.5, 25, 75 mg/kg bw/d	For 2 years, rats were given the test substance in corn oil via gavage	No significant increases in the frequency of neoplasms were found. Chronic inflammation of the mesenteric arteries was increased in males given 75 mg/kg bw.	^{6,35}

Table 9. Epidemiological Studies

Ingredient	Test Article/Dose	Procedure	Results	Reference
Bladder/Renal				
Caffeine	30+ cups coffee/wk, 3+ cups tea/wk	332 white male bladder cancer patients between the age of 21 and 84 with 686 population-based controls	A 2.5-fold increase in the risk of developing bladder cancer was observed in men who drank 30 or more cups of coffee ⁴⁶ /day	⁴⁶
Bladder/Renal				
Caffeine	Caffeinated coffee and tea (Control patients received 0 cups of coffee or tea, other dose levels included 1-20, 21-40, or 40+ cups/week)	424 bladder cancer patients identified through the Utah Cancer Registry, and 889 controls obtained through random digit dialing and the Health Care Financing Administration	Patients who drank more than 40 cups of coffee or tea a day had an increased risk of bladder cancer; for non-smokers, the odds ratio was doubled with consumption of one or more cups of caffeinated tea, smokers had a tripled odds ratio	⁴⁶
Caffeine	Coffee (caffeinated and decaffeinated), tea, cocoa, soda, artificial sweetener	826 bladder cancer patients; 792 randomly selected population controls matched by age, sex, and area of residence	No association was reported between Caffeine consumption and bladder cancer	⁴⁶
Caffeine	Coffee consumption (regular ground, instant, decaffeinated)	195 male and 66 women with lower urinary tract bladder cancer, identified in Hawaii between 1977 and 1986. Each case was matched for sex, age, and ethnic group (Caucasian or Japanese) to 2 population-based controls.	No association between duration and amount of coffee consumed and development of lower urinary tract cancer; inverse relationship between lower urinary tract cancer and the consumption of regular ground coffee ($p = 0.02$), but not with any other types of coffee	⁴⁶
Caffeine	Coffee consumption (caffeinated and decaffeinated), other methylxanthine-containing beverages	303 male and 61 female Italian bladder cancer patients	The relative risk was 1.2 for those who drank 1 cup of coffee or less/day; the relative risk for those who drank 3 or more cups/day was 1.5, those who drank 4 or more cups/day had a relative risk of 1.4. The results indicated a higher prevalence of coffee consumption in bladder cancer cases; however, the prevalence was not clearly dose-dependent.	⁴⁶
Breast				
Caffeine	up to 7 cups coffee/day	2651 newly-diagnosed breast cancer patients in the eastern US; 1,501 controls with nonmalignant conditions	No association between coffee consumption and breast cancer risk observed.	⁴⁶
Caffeine	Consumption of coffee, tea, soda, chocolate, chocolate drinks (amount not reported)	1617 breast cancer patients, ages 20 to 79 in eastern New York; 1617 randomly selected controls matched with age, sex, and area of residence	No association between Caffeine consumption and breast cancer risk observed.	⁴⁶

Table 9. Epidemiological Studies

Ingredient	Test Article/Dose	Procedure	Results	Reference
Caffeine	Median Caffeine intake of 212 mg/d in women who developed breast cancer and 201 mg/d in women who remained free of the disease	34,800 postmenopausal women from Iowa were monitored from 1986-1990. Caffeine intake was assessed by food frequency questionnaire. 580 with breast cancer	No association between breast cancer occurrence and Caffeine intake.	⁴⁶
Caffeine	>100 mg Caffeine/d; 0.5 mmol/d	755 breast cancer patients under the age of 36 in the United Kingdom; 755 age-matched general population controls	No association between Caffeine consumption and breast cancer risk.	⁴⁶
Pancreas				
Caffeine	5 or more cups coffee/day	99 pancreatic cancer patients, aged 40-79 years in Sweden; 138 population controls and 163 hospital controls	No relation between coffee consumption and pancreatic cancer incidence reported	⁴⁶
Caffeine	Coffee (5+ cups/d), decaffeinated coffee (2+ cups/d), tea (1+ cups/day)	150 Italian women with pancreatic cancer, 605 controls with acute, non-neoplastic diseases unrelated to coffee consumption	Increased incidence of pancreatic cancer in patients who drank 2+ cups coffee/day (RR=1.72, 95% CI 0.95-3.11); RR of 1.44 (95% CI 0.74-2.80) for those who drank 3-4 cups/day and 1.06 (95% CI 0.41-2.70) who drank 5+ cups/day	⁴⁶
Reproductive Organs				
Caffeine	Coffee (5+ cups/d), decaffeinated coffee (5+ cups/d), tea (5+ cups/day)	290 patients with ovarian cancer in the United States; 580 controls with non-malignant conditions of acute onset and 476 controls with cancer of other sites	Increased risk of ovarian cancer associated with drinking 4-5 cups coffee/d; RR=1.1 (95% CI 0.6-2.0) using the controls with non-malignant conditions and RR=1.0 (95% CI 0.5-1.8) using the controls with cancer. No association between ovarian cancer and decaffeinated beverage consumption	⁴⁶
Caffeine	Caffeinated coffee, decaffeinated coffee, and tea consumption (amount not reported)	201 patients with vulvar cancer; 342 community controls	Elevated risk in patients who drank 1, 2, or 4 cups of coffee, but not 3 cups/day. No association between vulvar cancer and decaffeinated coffee seen.	⁴⁶
Caffeine	Coffee, tea, and Caffeine consumption (amount not reported)	362 white Utah men with prostate cancer, 685 age-matched controls	No association between prostate cancer risk and coffee/tea/Caffeine consumption	⁴⁶
